3 **1 Abstract**

4  
5  
6 2 The extensive use of nano metal-based products increases the chance of their release into  
7  
8 3 aquatic environments, raising the question whether they can pose at risk aquatic biota and the  
9  
10 4 associated ecological processes. Aquatic microbes, namely fungi and bacteria, play a key role  
11  
12 5 in forested streams by decomposing plant litter from terrestrial vegetation. Here, we  
13  
14 6 investigated the effects of nano copper oxide and nano silver on leaf litter decomposition by  
15  
16 7 aquatic microbes and the results were compared with the impacts of their ionic precursors.  
17  
18 8 Alder leaves were immersed in a stream of Northwest Portugal to allow microbial  
19  
20 9 colonization before being exposed in microcosms to increased nominal concentrations of  
21  
22 10 nano metals (CuO, 100, 200 and 500 ppm; Ag, 100 and 300 ppm) and ionic metals (CuCl<sub>2</sub>,  
23  
24 11 10, 20 and 30 ppm; AgNO<sub>3</sub>, 5 and 20 ppm) for 21 days. Results showed that rates of leaf  
25  
26 12 decomposition decreased with exposure to nano and ionic metals. Negative effects of nano  
27  
28 13 and ionic metals were stronger on bacterial biomass than on fungal biomass. Fungal  
29  
30 14 sporulation rates strongly decreased with increased concentrations of nano and ionic metals.  
31  
32 15 These effects were accompanied by shifts in the structure of fungal and bacterial  
33  
34 16 communities based on DNA fingerprints and fungal spore morphology. The impacts of metal  
35  
36 17 nanoparticles on leaf decomposition by aquatic microbes were less pronounced compared to  
37  
38 18 their ionic forms, despite metal ions were applied at one order of magnitude lower  
39  
40 19 concentrations. Overall, results indicate that the increased release of nano metals to the  
41  
42 20 environment may affect aquatic microbial communities with impacts on organic matter  
43  
44 21 decomposition in streams.

## 1 Introduction

Owing to the rapid growth of nanotechnology-based industries enormous amounts of nanomaterials are being manufactured and utilized since the past decade [1]. Nano metal-based products have become part of our regular life in the form of cosmetics [42], antimicrobial paints [21], textile fabrics [56] and electronic devices [26]. Nano metals are also employed in biomedical and pharmaceutical applications, like cancer therapy, protein detection, tissue engineering, drug delivery and gene therapy [46]. With the accelerated usage of nanoparticles, aquatic ecosystems most likely will serve as terminal repository for the discharged nanomaterials. For instance, the engineered nanoparticle TiO<sub>2</sub> was detected in aquatic environments as a consequence of being leached from the paint of house facades into the neighbouring stream [21]. Hence, the research pertaining to impacts of nanoparticles and its ionic forms on aquatic biota has become a priority.

Ionic metals are used as precursors for production of many nanomaterials; for instance, silver nitrate and copper chloride are known to be the ionic precursors of nano silver and nano copper oxide, respectively [47, 52]. A number of studies have reported toxicity of metal ions against aquatic organisms ranging from microbes to vertebrates [3, 5, 14], but less is known about the effects of their nanoparticle forms (but see e.g., [2, 32]).

Nano silver and nano copper oxide are used widely (e.g., medical research/applications [31, 43] and textiles [56]) and are becoming the focus of toxicological investigations. These nanoparticles can have toxic effects on various organisms, including yeasts [23], bacteria [24], fungi [25], the marine diatom *Thalassiosira weissflogii* [28], *Chlamydomonas* [45] and fish, like zebrafish [17], and may also pose risks to human health [22, 36]. However, the existing data on the effects of nano-sized silver and copper oxide are mainly based on individual responses of organisms and are clearly insufficient to predict its

1 impacts on biotic communities (but see reports from Bradford et al. [6] and Shah et al. [48]  
2 for estuarine and soil bacterial assemblages, respectively) and ecosystem processes.

3 In freshwaters, plant-litter decomposition is a key ecosystem process associating  
4 riparian vegetation with microbial and invertebrate activities [41, 39]. Fungi, mainly aquatic  
5 hyphomycetes, have been distinguished as dominant microbial decomposers [37] and are  
6 responsible for transferring carbon and energy from plant litter to higher trophic levels in  
7 streams [15]. Bacteria have been recognized to play a role after partial breakdown of plant  
8 material [37]. Previous studies demonstrated that litter decomposition is sensitive to changes  
9 in water chemistry [12, 37, 41] and this integrative process was proposed as a functional  
10 measure to assess the health of freshwater ecosystems [38, 41].

11 Even though the ionic forms of metals have been reported to affect litter decomposition and  
12 the associated communities in freshwaters (e.g. [9, 33, 50]), studies exploring the impacts of  
13 nano metals on this ecosystem process are virtually unknown. The aim of this study was to  
14 investigate the effects of nano copper oxide and nano silver, and their ionic precursors, on  
15 leaf litter decomposition by freshwater microbial communities. We used stream-dwelling  
16 microbial communities in microcosms to mimic the natural environment under controlled  
17 conditions, and the measured parameters were leaf mass loss, fungal and bacterial biomass  
18 and diversity, and fungal reproduction.

## 21 **Material and Methods**

### 22 **Field experiment**

23 The sampling site is located at the Maceira stream (N 41°45'58.79", W 8°08'49.39",  
24 altitude 867 m) in the Peneda-Gerês National Park (Northwest Portugal). At the sampling  
25 site, the stream is 0.3-0.5 m deep and 0.5-1.0 m wide and the geological substratum is

1 constituted by granitic rocks, pebbles, gravels and sand. The dominant riparian vegetation  
2 includes *Quercus pyrenaica* Wild, *Quercus robur* L., *Chamaecyparis* sp. and *Ilex aquifolium*  
3 L.

4 Leaves of *Alnus glutinosa* (L.) Gaertn. (alder) were collected from a single Autumn  
5 tree and air dried at room temperature. The leaves were soaked in deionised water and cut  
6 into 12 mm-diameter disks. Sets of 40 disks were placed into each of 105 fine mesh bags (15  
7 × 15 cm, 0.5-mm mesh size, to prevent invertebrate colonization) that were immersed in the  
8 stream for 7 days to allow microbial colonization. After 30 min of leaf immersion, 3  
9 randomly selected leaf bags were retrieved and transported to the laboratory to determine  
10 initial leaf mass.

11 Conductivity and pH of the stream water were measured *in situ* with field probes  
12 (Multiline F/set 3 no. 400327, WTW, Weilheim, Germany). Stream water samples were  
13 collected into sterile dark glass bottles, transported in a cold box (4°C) to the laboratory to  
14 determine the concentrations of nitrate (HACH kit, programme 351), nitrite (HACH kit,  
15 programme 371) and phosphate (HACH kit, programme 490) using a HACH DR/2000  
16 photometer (HACH, Loveland, CO).

#### 18 Microcosm experiment

19 After retrieval from the stream, leaf disks from each of 102 bags were rinsed with  
20 deionised water and placed into 150 mL sterile Erlenmeyer flasks with 80 mL of sterile  
21 stream water (121°C, 20 min). Stream water had a pH of 5.9, a conductivity of 16  $\mu\text{S cm}^{-1}$ ,  
22 and contained 40  $\mu\text{g L}^{-1}$  N- $\text{NO}_3^-$ , 2  $\mu\text{g L}^{-1}$  N- $\text{NO}_2^-$  and 20  $\mu\text{g L}^{-1}$  P- $\text{PO}_4^{3-}$ . Stream water was  
23 supplemented with increasing nominal concentrations of nano metals or ionic metals as  
24 follows: 0, 100, 200 and 500 ppm of nano copper oxide (CuO nanopowder <50 nm, 99.5%);  
25 0, 100 and 300 ppm of nano silver (Ag nanopowder, <100 nm, 99.5%); 0, 10, 20 and 30 ppm

1 of ionic copper ( $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ , > 99%); and 0, 5 and 20 ppm of ionic silver ( $\text{AgNO}_3$ , > 99%).  
2 Nano and ionic metals were purchased from Sigma-Aldrich (St. Louis, MO). Stock  
3 suspensions of the two nano metals were sonicated (Branson 2510 sonication bath, Danbury,  
4 CT, USA) for 30 min in dark before used [18]. The pH of stock suspensions of nano metals  
5 and stock solutions of ionic metals were adjusted to  $6.0 \pm 0.2$ .

6 All microcosms were kept under shaking (150 rpm) at  $13^\circ\text{C}$ , and nanoparticle  
7 suspensions and ionic metal solutions were renewed every 7 days. After 7, 14 and 21 days of  
8 exposure, a set of 33 microcosms (3 replicates of each treatment per time) was sacrificed and  
9 leaf disks were freeze dried to determine leaf mass loss, microbial biomass and diversity as  
10 described below. In addition, the content of 3 leaf bags was used to determine leaf mass loss  
11 and microbial parameters at the beginning of microcosm experiment.

#### 12 13 Fungal sporulation rates

14 After 21 days of exposure to the nano and ionic metals, suspensions of released fungal  
15 conidia from each replicate microcosm were mixed with Triton X-100 (40  $\mu\text{l}$  of 15%), to  
16 avoid conidial adherence to the flask, and the conidia were fixed with 2% formaldehyde.  
17 Then, appropriate aliquots of conidial suspensions were filtered (5  $\mu\text{m}$  pore size, Millipore,  
18 Billerica, MA) and stained with 0.05% cotton blue in lactic acid. Conidia of aquatic  
19 hyphomycetes were identified and counted under a light microscope (Leica Biomed,  
20 Heerbrug, Switzerland) at  $400\times$  magnification.

#### 21 22 Microbial biomass

23 Concentration of ergosterol was measured to estimate fungal biomass associated with  
24 decomposing leaves [13, 37]. Lipids were extracted from sets of 6 leaf disks per replicate by  
25 heating (30 min,  $80^\circ\text{C}$ ) in 0.8% KOH-methanol and the extract was purified by solid-phase

1 extraction and eluted in isopropanol. Ergosterol was quantified by high-performance liquid  
2 chromatography (HPLC) using a LiChrospher RP18 column (250 × 4 mm, Merck) connected  
3 to a Beckmann Gold liquid chromatographic system. The system was run isocratically with  
4 HPLC-grade methanol at 1.4 mL min<sup>-1</sup> and 33°C. The peaks of ergosterol were detected at  
5 282 nm and standard series of ergosterol (Sigma) in isopropanol were used to estimate the  
6 ergosterol concentration in the samples. Ergosterol concentration was converted to fungal  
7 biomass assuming 5.5 µg ergosterol mg<sup>-1</sup> mycelial dry mass [13].

8 To estimate bacterial biomass, sets of 4 leaf disks per replicate were placed into 15  
9 mL falcon tubes with of 10 mL phosphate buffered formalin (2% final concentration) and  
10 kept at 4°C until processed. Bacterial cells were dislodged from leaf disks by sonication for 5  
11 min. Aliquots of 2 mL of appropriate dilutions of bacterial suspensions were incubated with  
12 4',6-diamidino-2-phenylindole (DAPI, 50 µL of 0.1 mg mL<sup>-1</sup>; Molecular Probes) for 10 min  
13 in the dark, before filtered through black polycarbonate membranes (0.2 µm pore size, GTTP,  
14 Millipore Billerica, MA). Filters were mounted between two drops of immersion oil on  
15 grease free slides, covered with cover slips and bacterial cells were counted using a  
16 fluorescence microscope (Leitz Laborlux Heerbrug, Switzerland) at magnification of 1000×.  
17 Bacterial numbers were converted to bacterial biomass considering a mean bacterial biomass  
18 of 20 fg cell<sup>-1</sup> [34].

#### 19 20 Denaturing gradient gel electrophoresis

21 DNA was extracted from 3 leaf disks (pooling 2 half disks of each replicate) using the  
22 UltraClean Soil DNA kit (MoBio Laboratories, Solana Beach, CA, USA). The ITS2 region of  
23 fungal genomic rDNA was amplified with the primer pair ITS3GC and ITS4 [9, 53] and the  
24 V3 region of bacterial 16S rDNA was amplified with the primer pair 338F\_GC and 518R [9].  
25 The 40-bp GC tail on the 5' end of the forward primers ensured the amplicon separation by

1 denaturing gradient gel electrophoresis (DGGE). All primers were purchased from MWG  
2 Biotech AG. For polymerase chain reaction (PCR), 1x Go Taq Green Master Mix (Promega),  
3 0.8  $\mu$ M of each primer and 2  $\mu$ L of extracted fungal or bacterial DNA were mixed gently with  
4 nuclease free water in a final volume of 50  $\mu$ L. PCR was carried out in the iCycler Thermal  
5 Cycler (BioRad Laboratories, Hercules, CA, USA). DNA amplification programme was  
6 started with a denaturation for 5 min at 94°C, followed by 36 cycles of denaturation for 30 s  
7 at 94°C, primer annealing for 30 s at 55°C and extension for 1 min at 72°C, concluding with  
8 an extension for 3 min at 72°C [9]. The PCR products were separated by DGGE using the  
9 DCode™ Universal Mutation Detection System (BioRad Laboratories, Hercules, CA, USA).  
10 For fungal DNA, 20–40  $\mu$ L from the amplified products of 380–400 bp were loaded on 8%  
11 (w/v) polyacrylamide gel in 1x Tris–Acetate–EDTA (TAE) with a denaturing gradient from  
12 30% to 70% (100% denaturant corresponds to 40% formamide and 7 M urea). For bacterial  
13 DNA, 20  $\mu$ L from the amplified products of 200 bp were loaded on 8% (w/v) polyacrylamide  
14 gels in 1x TAE with a denaturing gradient from 35% to 80%. DNA mixtures of 5 species of  
15 fungi or bacteria were used to calibrate the gels. The gels were run at 55 V for 16 h at 56°C  
16 and stained with 1x GelStar (Lonza Rockland, Inc., USA). The gel images were captured  
17 under UV light in a transilluminator Eagle eye II (Stratagene, La Jolla, CA, USA).

#### 18 Leaf mass loss

19 To determine leaf mass loss, freeze-dried leaf disks from each replicate before and  
20 after stream colonization, and after microcosm exposure were weighed to the nearest 0.001  
21 mg.

#### 22 Nano metals in stock suspensions

1  
2  
3 1 The nano metals in suspensions were analysed by UV-visible spectrophotometry (UV  
4  
5 2 – 1700 PharmaSpec, Shimadzu, Kyoto, Japan) and by scanning electron microscopy (SEM,  
6  
7 3 Leica Cambridge S 360, Cambridge, UK) coupled to an energy dispersive X-ray  
8  
9 4 microanalysis setup (EDX, 15 KeV). For SEM analysis, 20 µl of stock suspension of each  
10  
11 5 nanometal was mounted on a clean grease free slide in dark, air dried and coated with gold in  
12  
13 6 vacuum by using a Fisons Instruments SC502 sputter coater. Nano silver and nano copper  
14  
15 7 oxide showed plasmon picks at 416 nm and 359 nm, respectively. Scanning electron  
16  
17 8 microscopy confirmed the size of copper oxide nanoparticles (30 to 50 nm) and silver  
18  
19 9 nanoparticles (near to 100 nm). The presence of Cu and O in copper oxide nanoparticles and  
20  
21 10 Ag in silver nanoparticles was confirmed by EDX (Fig. 1A and B). Additional picks were  
22  
23 11 found: Au from the coated gold, Si probably from the glass slide, and Na, Ca and Mg  
24  
25 12 probably from the stream water.  
26  
27  
28  
29  
30  
31  
32  
33

#### 34 14 Statistical analyses

35  
36 15 Rates of leaf decomposition (k) were estimated according to the exponential model as  
37  
38 16 follows:  $W_t = W_0 \times e^{-kt}$ , where  $W_t$  is the leaf dry mass remaining at time t,  $W_0$  is the initial  
39  
40 17 leaf dry mass and t is the time in days. Regression lines of ln-transformed values of leaf dry  
41  
42 18 mass against time were compared by analysis of covariance (ANCOVA [55]). Three-way  
43  
44 19 analysis of variance (3-way ANOVA [55]) was used to determine the effects of time and  
45  
46 20 concentration of nano and ionic forms of each metal on fungal and bacterial biomass. Two-  
47  
48 21 way ANOVA was used to test the effects of concentration of nano and ionic forms of each  
49  
50 22 metal on fungal sporulation rate, fungal diversity and contribution of aquatic hyphomycete  
51  
52 23 species to the total conidial production after 21 days of exposure. Significant differences  
53  
54 24 between control and treatments were analysed by Bonferroni post-tests [55]. When needed,  
55  
56 25 data were ln-transformed to achieve normal distribution and homocedasticity [55]. Univariate  
57  
58  
59  
60

1 analyses were performed with Statistica 6.0 (Statsoft, Inc., Tulsa, OK, USA).

2 Cluster analyses of fungal and bacterial communities based on relative intensity of  
3 each DGGE band was done by Unweighted Pair-Group Method Average (UPGMA) using the  
4 Pearson correlation coefficient [12]. Each band in the gel was considered one operational  
5 taxonomic unit (OTU). Gel and cluster analyses were done with the GelCompar II program  
6 (Applied Maths, Sint-Martens-Latem, Belgium).

## 9 **Results**

### 10 Nano and ionic metals reduce microbially-mediated leaf litter decomposition

11 The decomposition rate of alder leaves was high corresponding to  $0.037 \text{ day}^{-1}$  (Table  
12 1). The exposure to nano or ionic metals led to a significant decrease in leaf decomposition  
13 rate (ANCOVA,  $P < 0.05$ ). The lowest decomposition rates were found at the highest  
14 concentrations of nano and ionic silver ( $k = 0.021 \text{ day}^{-1}$  for 300 ppm nano silver and 20 ppm  
15 ionic silver) or nano copper oxide and ionic copper ( $k = 0.017 \text{ day}^{-1}$  and  $0.015 \text{ day}^{-1}$  for 500  
16 ppm of nano copper oxide and 30 ppm of ionic copper, respectively).

17 After 7 days of colonization in the stream, fungal biomass on decomposing leaves was  
18  $10 \text{ mg g}^{-1}$  leaf dry mass and increased to  $53 \text{ mg g}^{-1}$  leaf dry mass after 21 days in control  
19 microcosms (Fig. 2A and 2B). Concentrations of nano and ionic forms of silver or copper and  
20 exposure time had negative effects on fungal biomass (three-way ANOVAs,  $P < 0.05$ ; Table  
21 2). After 21 days of exposure to the highest concentration of nano silver (Fig. 2A) or nano  
22 copper oxide (Fig. 2B) a 40% inhibition of fungal biomass was found (Bonferroni tests,  
23  $P < 0.05$ ). Fungal biomass was inhibited earlier by exposure to the highest concentrations of  
24 ionic silver ( $15$  and  $9 \text{ mg g}^{-1}$  leaf dry mass at 20 ppm for 14 and 21 days, respectively;  
25 Bonferroni tests,  $P < 0.05$ ; Fig. 2A) or ionic copper ( $24$  and  $18 \text{ mg g}^{-1}$  leaf dry mass at 30 ppm

1 for 14 and 21 days, respectively; Bonferroni tests,  $P < 0.05$ ; Fig. 2B). A significant decrease in  
2 fungal biomass was also observed at the longest exposure time to the lowest concentrations of  
3 ionic silver ( $17 \text{ mg g}^{-1}$  leaf dry mass at 5 ppm; Bonferroni test,  $P < 0.05$ ; Fig. 2A) or ionic  
4 copper ( $30$  and  $18 \text{ mg g}^{-1}$  leaf dry mass at 10 and 20 ppm for 21 days, respectively;  
5 Bonferroni test,  $P < 0.05$ ; Fig. 2B).

6 Before microcosm exposure, bacterial biomass on leaves was  $0.02 \text{ mg g}^{-1}$  leaf dry  
7 mass and increased to  $0.26 \text{ mg g}^{-1}$  leaf dry mass after 21 days in microcosms (Fig. 3A and  
8 3B). The exposure to all concentrations of nano and ionic silver led to a significant decrease  
9 in bacterial biomass at all times (three-way ANOVA; Bonferroni test,  $P < 0.05$ , Table 2, Fig.  
10 3A) with strongest effects for silver ions ( $0.01 \text{ mg g}^{-1}$  leaf dry mass). Nano copper oxide and  
11 ionic copper concentrations and time also had significant inhibitory effects on bacterial  
12 biomass (three-way ANOVA,  $P < 0.05$ ; Table 2). The exposure to the highest concentrations  
13 of nano copper oxide (200 and 500 ppm) or ionic copper (20 and 30 ppm) led to a significant  
14 decrease in bacterial biomass at all times, whereas the lowest tested concentrations of these  
15 toxicants (100 ppm of nano copper oxide and 10 ppm of ionic copper) decreased the biomass  
16 only after 14 and 21 days of exposure (Bonferroni test,  $P < 0.05$ , Fig. 3B).

17 In control microcosms, sporulation rate of aquatic hyphomycetes attained  $245 \times 10^3$   
18 spores  $\text{g}^{-1}$  leaf dry mass  $\text{day}^{-1}$  and was significantly inhibited by exposure for 21 days to all  
19 concentrations of nano and ionic forms of silver or copper (two-way ANOVA,  $P < 0.05$ ; Fig.  
20 4A and B).

## 21 Nano and ionic metals affect the structure of microbial decomposer community

22 Based on conidial morphology, a total of 11 aquatic hyphomycete species were  
23 identified on decomposing leaves after 21 days in control microcosms (Table 3). The  
24 exposure to nano and ionic metals decreased fungal species richness, particularly in the case  
25

1  
2  
3 1 of copper (5 species in treatments with concentrations  $\geq 200$  ppm of nano copper and 4  
4  
5 2 species with 30 ppm of ionic copper; Table 3). In addition, nano and ionic metals led to shifts  
6  
7  
8 3 in fungal species composition (Table 3). In control, *Articulospora tetracladia* (51.2%) was  
9  
10 4 the dominant species followed by *Flagellospora* sp. (32.8%) (Table 3). The exposure to nano  
11  
12 5 silver, nano copper and ionic copper significantly increased the contribution of *A. tetracladia*  
13  
14 6 to overall conidial production (two-way ANOVAs, Bonferroni tests,  $P < 0.05$ ), whereas ionic  
15  
16 7 silver did not lead to any significant change (Table 3). The exposure to nano and ionic metals  
17  
18 8 significantly decreased the contribution of *Flagellospora* sp. (Bonferroni test,  $P < 0.05$ ; Table  
19  
20 9 3) but increased that of *Heliscus lugdunensis* (Bonferroni test,  $P < 0.05$ ; Table 3).

21  
22  
23  
24 10 DNA fingerprinting based on DGGE showed that fungal and bacterial communities  
25  
26 11 were affected by nano and ionic metals (Fig. 5A and B, Table 3). Thirty one fungal OTUs  
27  
28 12 and 36 bacterial OTUs were found in control communities (Fig. 5A and B, Table 3). The  
29  
30 13 number of fungal or bacterial OTUs decreased with increasing concentrations of nano or  
31  
32 14 ionic metals, particularly in the case of the latter form of the toxicants, with maximum  
33  
34 15 reduction at the highest concentration of ionic silver (Fig. 5A and B, Table 3). Cluster  
35  
36 16 analysis of fungal communities exposed to the highest ionic silver concentration formed an  
37  
38 17 outgroup (Fig. 5A). Further, fungal communities exposed to nano silver clustered together  
39  
40 18 and were separated from control communities or communities exposed to other treatments.  
41  
42 19 Cluster analysis of bacteria discriminated 3 groups: control communities, communities  
43  
44 20 exposed to silver and communities exposed to copper (Fig. 5B). Bacterial communities  
45  
46 21 exposed to nano and ionic forms of each metal were further separated.

## 24 Discussion

25 Due to the small size and reactive surface characteristics of nanoparticles, they are

1  
2  
3 1 prone to aggregation and sorption onto organic materials [19], such as submerged plant  
4  
5 2 detritus in streams. Therefore, a close interaction between nano metals and benthic microbes  
6  
7  
8 3 involved in plant litter decomposition is expected to occur. Our study depicted that nano and  
9  
10 4 ionic metals can have impacts on microbial communities and reduce leaf litter decomposition  
11  
12 5 in freshwater ecosystems. The negative effects of metal ions, such as zinc, copper and  
13  
14 6 cadmium, on freshwater microbial decomposers have been often reported [9, 11, 12, 27, 29];  
15  
16 7 however, very little is known on the putative impact of nano metals. In our study, the  
17  
18 8 exposure to elevated concentrations of nano and ionic metals affected microbial biomass on  
19  
20 9 decomposing leaves. The biomass of bacteria was strongly inhibited even at short exposure  
21  
22 10 times (7 days). Indeed, many nano metals are known to have anti-bacterial properties (< 100  
23  
24 11 ppm in axenic cultures [54]). However, negligible effects of nano silver or nano copper on  
25  
26 12 bacterial abundance, diversity (as fatty acid methyl-ester or DGGE profiles) or activity (as  
27  
28 13 metabolic profile) are reported in soil [48] and estuarine [6] communities. The discrepancy  
29  
30 14 between our results and the latter studies may be explained by the two order of magnitude  
31  
32 15 lower concentrations of the nano metals used in the two cited studies. Also, differences in  
33  
34 16 environmental conditions, such as pH, temperature and oxygen availability [44], as well as  
35  
36 17 nanoparticle properties (e.g., size [8]) might account for different results in different studies  
37  
38 18 and is worthy of further investigation.

39  
40  
41 19 Here we found that biomass of bacteria was more sensitive to nano and ionic silver or  
42  
43 20 copper than that of fungi. This agrees with earlier reports showing that, contrarily to bacterial  
44  
45 21 biomass [10, 11], fungal biomass is not very sensitive to moderate metal stress and decline  
46  
47 22 only under high stress levels [10, 11, 33]. This might be due to the higher growth rates of  
48  
49 23 bacteria on decomposing leaves than those of fungi [37, 39]. The structure of bacterial  
50  
51 24 communities, based on DNA fingerprint, also appeared to respond better than fungal  
52  
53 25 communities to the presence of these toxicants, because bacterial communities discriminated  
54  
55  
56  
57  
58  
59  
60

1 well the stress imposed by ionic and nano forms of silver and copper. It is also conceivable  
2 that the response pattern of fungal communities become clearer at longer exposure times, as  
3 shown by Duarte et al. [9] in microbial communities exposed to copper and zinc ions.  
4 Moreover, a differential response of aquatic microbial communities to each nano metal and  
5 respective ionic form was found, suggesting different modes of action of these toxicants. This  
6 is supported by distinct gene expression profiles in zebrafish gills after exposure to nano or  
7 ionic metals [17].

8         The analysis of aquatic hyphomycete communities based on identification of released  
9 spores from decomposing leaves also showed shifts in community composition after  
10 exposure to nano and ionic metals. For instance, the dominant fungal species *A. tetracladia*  
11 increased its contribution to the total released conidia after exposure to nano silver and ionic  
12 copper, but not to ionic silver or nano copper oxide. Moreover, the co-dominant species  
13 *Flagellospora* sp. was inhibited by exposure to nano or ionic metals, being replaced by *H.*  
14 *lugdunensis* at the highest concentrations. *Articulospora tetracladia* and *H. lugdunensis* are  
15 reported to occur in metal contaminated streams [20, 40] and some strains of these species  
16 were found to be resistant to high concentrations of metals [7]. The shift in species  
17 composition in this study probably indicates a change towards a better-adapted community,  
18 which may play an ecological role under the stress imposed by nano metals and/or their ionic  
19 precursors.

20         The significant reduction in leaf decomposition rate by stream-dwelling microbes in  
21 the presence of nano or ionic metals was probably due to the observed decrease in fungal and  
22 bacterial diversity and activity on leaf litter. Although biomass of fungi was apparently less  
23 affected by these stressors than that of bacteria, fungal biomass on decomposing leaves was  
24 two orders of magnitude higher. This agrees with previous studies pointing to a dominant role  
25 of fungi during litter decomposition in freshwaters [37, 39]. Therefore, it is conceivable that

1  
2  
3 1 the observed reduction in litter decomposition was mainly due to the negative effects of nano  
4  
5 2 and ionic metals on fungal activity. Unfortunately, we do not have data on the activity of  
6  
7  
8 3 plant litter degrading enzymes in aquatic fungi under nano or ionic metal stress. However, in  
9  
10 4 the white rot fungus *Trametes versicolor*, the production of lignocellulose degrading  
11  
12 5 enzymes, such as  $\beta$ -glucosidase, cellobiohydrolase and  $\beta$ -xylosidase, decreased by the  
13  
14 6 presence of ionic copper and aggregated nanoparticles [49].  
15  
16

17 7 In our study, the impacts of nano and ionic metals were more pronounced on fungal  
18  
19 8 sporulation than on fungal biomass or diversity. This has ecological implications because if  
20  
21 9 fungal reproductive output is affected, it may further compromise fungal dispersal and  
22  
23 10 survival in freshwaters with impacts to leaf eating invertebrates that dependent on fungal  
24  
25 11 activity. Moreover, sporulation rate was one of the most sensitive microbial parameters to  
26  
27 12 nano or ionic metals. Also, other studies point to reproduction of aquatic hyphomycetes as a  
28  
29 13 sensitive measure of water quality [9, 11, 27] with possible applications in stream monitoring  
30  
31 14 programmes.  
32  
33  
34

35  
36 15 Even though we used concentrations of ionic metals one order of magnitude lower  
37  
38 16 than those of nano metals, the negative effects of ionic forms were more pronounced  
39  
40 17 compared to their nano forms. Also, the toxicity of nano copper oxide to the protozoa  
41  
42 18 *Tetrahymena thermophila* ( $EC_{50,14h} = 128$  ppm) was 120 times lower than that of the ionic  
43  
44 19 copper [30]. This may be attributed to the low bioavailability of nano forms in water. The  
45  
46 20 toxicity of nano metals to bacteria [18], aquatic algae [2], and to the eukaryotic model yeast  
47  
48 21 *Saccharomyces cerevisiae* [23] was attributed to soluble metal ions originating from the  
49  
50 22 metal oxide particles. Conversely, others found that the toxicity of nano copper and silver in  
51  
52 23 zebrafish and *Daphnia pulex* is unlikely to be merely explained by particle dissolution [16].  
53  
54 24 Therefore, more investigation on the mechanisms of action of nanoparticles is needed to  
55  
56 25 clarify this aspect.  
57  
58  
59  
60

1  
2  
3 1  
4  
5  
6 2 The effects of nano copper oxide seemed to be stronger than those of nano silver on  
7  
8 3 leaf decomposition rate, bacterial biomass, fungal diversity and reproduction. However, it  
9  
10 4 should be taken into account that the size of metal nanoparticles used in our study was lower  
11  
12 5 for nano copper oxide (30-50 nm) than for nano silver (near to 100 nm). Data from literature  
13  
14 6 have shown that nano metal toxicity to several cell lines [35, 22] and organisms, including  
15  
16 7 aquatic species of different trophic levels, tend to increase with the decrease of particle size  
17  
18 8 [51, 18]. However, the toxicity of nano metals does not appear to be a generic response to  
19  
20 9 exposure to nanosized particles; rather, it seems that particular nano metals have an intrinsic  
21  
22 10 property that confers toxicity [22].  
23  
24  
25  
26

27 11 Overall, results provide the novel information that nano metals are potent to pose risks  
28  
29 12 to microbial communities that drive plant litter decomposition in streams by reducing  
30  
31 13 diversity and activity of fungi and bacteria. Moreover, our findings suggest that biomass of  
32  
33 14 aquatic bacteria and sporulation of aquatic fungi might be useful tools in ecotoxicological  
34  
35 15 studies to assess nano or ionic metal stress. Although the negative effects of ionic forms were  
36  
37 16 more pronounced compared to their nano forms, accumulation or adsorption of nano metals  
38  
39 17 to microbial cells is conceivable to occur [4]. If so, nano metals may enter aquatic detritus  
40  
41 18 foodwebs with impacts to higher trophic levels. This study clearly indicates emerging risks to  
42  
43 19 aquatic microbiota and associated ecosystem processes due to increasing industrial scale  
44  
45 20 production and usage of nano and ionic metal-based products.

1 **Table 1** Effects of nano and ionic metals on decomposition rates (k) of alder leaves

Treatments	k (day <sup>-1</sup> ) ± SE	W <sub>0</sub> (%)	r <sup>2</sup>
Control	0.037 ± 0.004	105.6	0.86
AgNP1	0.024 ± 0.003*	98.6	0.86
AgNP2	0.021 ± 0.003*	99.4	0.81
Ag1	0.022 ± 0.003*	97.3	0.79
Ag2	0.021 ± 0.003*	97.1	0.84
CuONP1	0.021 ± 0.002*	98.0	0.87
CuONP2	0.019 ± 0.002*	98.5	0.86
CuONP3	0.017 ± 0.002*	98.7	0.87
Cu1	0.022 ± 0.003*	97.8	0.83
Cu2	0.018 ± 0.002*	96.9	0.88
Cu3	0.015 ± 0.002*	95.8	0.75

2 AgNP1: 100 ppm nano Ag; AgNP2: 300 ppm nano Ag; Ag1: 5 ppm Ag<sup>+</sup>; Ag2: 20 ppm Ag<sup>+</sup>;  
 3 CuONP1: 100 ppm nano CuO; CuONP2: 200 ppm nano CuO; CuONP3: 500 ppm nano CuO;  
 4 Cu1: 10 ppm Cu<sup>2+</sup>; Cu2: 20 ppm Cu<sup>2+</sup>; Cu3: 30 ppm Cu<sup>2+</sup>; Control: without addition of any form  
 5 of metals nd, not detected. \*, treatments that differ significantly from control (ANCOVA,  
 6 Bonferroni test, *P* < 0.05). SE: standard error; r<sup>2</sup>: coefficient of determination; W<sub>0</sub>: initial leaf dry  
 7 mass.

**Table 2** ANOVAs of effects of exposure time, nano and ionic metal concentrations on fungal biomass, bacterial biomass and fungal sporulation (only significant effects are shown)

Parameter	Effect	d.f.	<i>F</i>	<i>P</i> -value
Fungal biomass				
Silver				
	Time	4	30.2	<0.0001
	Nano Ag	2	3.4	<0.05
	Ag <sup>+</sup>	2	26.4	<0.0001
Copper				
	Time	4	41.7	<0.0001
	Nano CuO	3	3.1	<0.05
	Cu <sup>2+</sup>	3	7.5	<0.0005
Bacterial biomass				
Silver				
	Time	4	191.8	<0.0001
	Nano Ag	2	31.4	<0.0001
	Ag <sup>+</sup>	2	101.1	<0.0001
Copper				
	Time	4	280.2	<0.0001
	Nano CuO	3	82.4	<0.0001
	Cu <sup>2+</sup>	3	82.0	<0.0001
Fungal sporulation rate (21 days)				
Silver				
	Nano Ag	2	371.0	<0.0001
	Ag <sup>+</sup>	2	646.6	<0.0001
Copper				
	Nano CuO	3	360.5	<0.0001
	Cu <sup>2+</sup>	3	364.9	<0.0001

**Table 3** Microbial diversity on decomposing leaves as number and composition of fungal sporulating species and number of fungal and bacterial OTUs from DGGE fingerprints after 21 days of exposure to increasing concentrations of nano or ionic metals in microcosms

Species	% of conidia in treatments
