3

### 4 **ABSTRACT**

5 A light weight concrete using granulated of corn cob (without corn) as aggregate is  
6 proposed in this research work. Taking into account that corn cob, after extracting the  
7 corn, is generally considered an agricultural waste, an interesting economic and  
8 sustainable benefit may result by using it as a building material. Therefore, it can be an  
9 alternative sustainable lightweight aggregate solution in comparison to the most current  
10 applied ones such as expanded clay, particles of cork, particles of expanded polystyrene  
11 (EPS), among other. The density, the compressive strength and the thermal insulation

12 properties of a corn cob concrete were experimentally quantified. An expanded clay  
13 concrete was also studied as reference. The obtained main results are presented and  
14 discussed indicating that the proposed corn cob concrete may have the adequate  
15 material properties required for a lightweight concrete for non-structural application  
16 purposes.

17

## 18 **1. INTRODUCTION**

19 The continuous search for more sustainable and economic processed solutions has been  
20 an important investigation topic of a broad research community worldwide. The  
21 resulting solutions can therefore be adapted by the industry thus leading to a more  
22 sustainable society. The building industry is not immune to this reality and huge efforts  
23 have been done in order to find alternative sustainable building materials and low  
24 technology methods, which result in a more sustainable and affordable construction  
25 complemented with the comfort standards required nowadays. The CO<sub>2</sub> emissions to  
26 the atmosphere, energy and water consumptions are some parameters that have  
27 significant impact in this equation. Reusing, opting for green building materials (which  
28 must be renewable, local, and abundant), retrofitting, choosing low technology methods  
29 and techniques are some practices that have given good results in this context [1-3].

30

31 The main scope of this research work consists on analyzing the potential use of corn cob  
32 granulate (without containing any corn, i.e. an agricultural waste) as a sustainable  
33 aggregate solution of lightweight concrete and as an alternative of common applied  
34 products such as: expanded clay, particles of expanded polystyrene (EPS), particles of  
35 cork or other lignocellulose wastes [4]. Since corn cob is generally considered an  
36 agricultural waste, an interesting economic and sustainable benefit may be achieved

37 through this proposed technological solution. Within the authors' knowledge the  
38 utilization of corn cob in concrete is quite novel, and is only known the use of corn cob  
39 ash in blended cement concretes [5-7].

40

41 Recently, different research works have been done focused on applying biological  
42 materials or different types of wastes within distinct building applications. Several  
43 authors [8-13] have already proposed using different agricultural product wastes such as  
44 bagasse, cereal, straw, corn stalk, corn cob, cotton stalks, kenaf, rice husks, rice, straw,  
45 sunflower hulls and stalks, banana stalks, coconut coir, bamboo, durian peel, oil palm  
46 leaves among others for product processing such as particleboard, hardboard and fiber  
47 board, and focusing on their thermal insulation ability. Others authors have been  
48 studying the technical potential of using others types of residue such as newspaper [14],  
49 honeycomb [15] or polymeric wastes [16] in the processing of different building  
50 components.

51

52 The lightweight corn cob concrete, presented in the present paper, was designed mainly  
53 for using it on regularization layers of pavements. Some of the expected requirements of  
54 a regularization layer building solution are: lightweight, insulation capacity (thermal  
55 and/or acoustic), and durability and economic are. Therefore, the density, the  
56 compressive strength and the thermal insulation performance were the material  
57 properties assessed of the proposed corn cob concrete within this research work. In  
58 order to evaluate and compare the performance of corn cob concrete, in parallel, was  
59 developed and tested a conventional lightweight concrete using expanded clay.

60

61 This paper is structured as follows, firstly, some possible lightweight concrete  
62 applications are presented and also some common lightweight aggregates are identified.  
63 Secondly, the compressive strength of corn cob and expanded clay concrete samples are  
64 assessed. The sample preparation and used equipment are described, and the obtained  
65 experimental results are presented and discussed. Thirdly, an alternative expedite  
66 experimental setup for thermal insulation performance assessment of light weight  
67 concrete samples is proposed. The inherent facility, the sample preparation, the used  
68 equipment and the test preparation are presented and described in detail. The obtained  
69 experimental results are presented, analyzed and discussed, whereas the thermal  
70 transmission coefficient of the two light weight concrete samples are quantified. Finally,  
71 the main conclusions of this research work are drawn.

72

## 73 **2. CONTEXT**

74 In order to guaranty the architectural design performance of a pavement, it is often used  
75 a regularization layer (detail 3 in Figure 1) as a technological building solution. In most  
76 of the cases, a cement mortar or a light weight concrete are the materials used in this  
77 regularization layer. This situation may occur on the pavements located on the ground  
78 floor (Figure 1.a), intermediate floors (Figure 1.b) or at the top floor (i.e. terraces),  
79 Figure 1.c. Associated to the regularization layer another layer of a thermal or / and  
80 acoustic insulation material is also commonly applied (see detail 4 in Figure 1). In the  
81 Portuguese context, thicknesses between 3 cm and 10 cm of the regularization layer are  
82 the most common solutions. This thickness depends on the location of the pavement, the  
83 type of the expected building floor utilization, among other factors. Lightweight,  
84 insulation capacity, durability and economic are some of the expected requirements for  
85 this constructive system (i.e. regularization and insulation layers).

86

87 Alternative solutions of the abovementioned constructive systems have been proposed  
88 and successfully applied. Some of those solutions employ lightweight aggregates such  
89 as expanded clay, particles of cork or particles of expanded polystyrene (EPS). This  
90 research work intends to propose another alternative solution of the above described  
91 system and focused on analyzing the potential of using particles of corn cob, Figures 2.a  
92 and 2.b, as lightweight aggregate for concrete. An expanded clay (Figure 2.c) concrete  
93 is adopted as reference. The analyzed material properties are the density, the  
94 compressive strength and the thermal insulation capacity.

95

### 96 **3. MECHANICAL BEHAVIOR ASSESSMENT**

97 At this stage, the compressive strength was the mechanical property analyzed because it  
98 is the more required for this context. Meanwhile, good compressive strength is also an  
99 indicator of good impact and abrasion capacities.

100

#### 101 **3.1. Sample preparation and test equipment**

102 The compressive strength of both corn cob and expanded clay concrete was assessed  
103 with cubic specimens of 15 cm edge length. In both cases, a weight ratio of 6:1:1 (i.e.  
104 lightweight aggregate: Portland cement: water) was adopted. This is a current applied  
105 ratio for regularization layer of expanded clay concrete applications in the Portuguese  
106 context. Figure 3 exemplifies some steps of the corn cob concrete sample processing  
107 such as adding the components (Figure 3.a), curing process (Figure 3.b) and the  
108 unmoulding step (Figure 3.c). Figure 3.b also indicates the corn cob concrete sample  
109 type used in the compression test (I, Figure 3.b) and the corn cob concrete sample type  
110 used in the thermal insulation performance test (II, Figure 3.b) related to section 4. On

111 the other hand, Figure 4 features the same steps of the expanded clay concrete sample  
112 processing. In both cases, the curing occurred under controlled thermal and hygrometric  
113 conditions.

114

115 At the age of 28 days, the samples were tested in terms of compression. Previously, they  
116 were measured and their mass was assessed by using a digital weighing-machine HP-  
117 20K. An ALPHA 3-3000D compression testing rig with an ultimate carrying capacity of  
118 3000 kN was used, as depicted in Figure 5.

119

### 120 **3.2. Experimental results and discussion**

121 The mass, density, ultimate compression load and the compressive strength were the  
122 material properties evaluated during the compressive test. The values of these properties  
123 are presented in Tables 1 and 2 for the corn cob and the expanded clay concrete  
124 specimens, respectively.

125

126 The average evaluated density of the corn cob concrete samples (ratio 6:1:1) was 382.2  
127 kg/m<sup>3</sup> which is lower than the respective material property of the expanded clay  
128 concrete samples (ratio 6:1:1), 576.3 kg/m<sup>3</sup>, see Tables 1 and 2. Since a low specific  
129 weight is probably one of the most important qualities for a regularization layer, i.e.  
130 without any special needs in terms of mechanical resistance (for a non-structural  
131 application), this experimental result corroborates the potential use of this agricultural  
132 waste product as a natural lightweight aggregate within concretes for regularization  
133 layers. The compressive strength of the expanded clay concrete (average value of 1360  
134 kN/m<sup>2</sup>, Table 2) is clearly higher than the correspondent property of the corn cob  
135 concrete (average value of 120 kN/m<sup>2</sup>, Table 1). The fact that the corn cob concrete

136 samples were not yet completely dried at the age of 28 days, and that the granulometry  
137 of the corn cob particles may require improvements in terms of range of dimensions and  
138 weight proportions; and the adopted corn cob concrete components ratio may be  
139 inadequate, may justify the above discrepancy. In order to figure out the impact of the  
140 corn cob concrete component ratio, four additional samples were casted (ratio 3:1:1)  
141 and tested under compression at the age of 28 days. The respective obtained  
142 experimental results are presented in Table 3. The compressive strength increased  
143 nearly 220% (from 120 kN/m<sup>2</sup>, Table 1; to 392.2 kN/m<sup>2</sup>, Table 3) associated to the fact  
144 of reducing the amount of corn cob particles in relation to the binder content (from  
145 6:1:1, Table 1, to 3:1:1, Table 3). However, the improvement on the compressive  
146 strength is still insufficient to reach the strength obtained with the expanded clay  
147 concrete (392.2 kN/m<sup>2</sup>, Table 3; against 1360 kN/m<sup>2</sup>, Table 2). At the same time, it was  
148 verified that there was a significant increment of the density (from 382.2 kg/m<sup>3</sup>, Table  
149 1, to 777.8 kg/m<sup>3</sup>, Table 3). It is worth to underline that the corn cob concrete samples  
150 processed with the ratio of 3:1:1 were also not completely dried at the age of 28 days.

151

152 Furthermore, an interesting resilience capacity of the corn cob concrete was noticed  
153 while carrying out the compression test.

154

#### 155 **4. THERMAL PERFORMANCE ASSEMENT**

156 In order to evaluate the thermal properties (e.g. the thermal transmission coefficient, U,  
157 or the thermal conductivity,  $\lambda$ ) of materials or building component systems, a thermal  
158 test cell is currently applied, which is a laboratory device. In this research work, an  
159 alternative experimental procedure based in [17] was applied since it can be applied in  
160 situ and also because it allows evaluating thermal properties of real scale building

161 component systems. The facilities, the sample preparation, the equipment and the test  
162 procedures are crucial for the success of this adopted experimental setup. Therefore, in  
163 the context of this paper, these aspects will be explained in detail within the following  
164 sections.

165

#### 166 **4.1. Facility and sample preparation**

167 A confined room with 4.00 m × 3.00 m × 2.54 m (length × width × height) was used as  
168 an alternative expedite solution of a thermal test cell, Figure 6.a. This room must have  
169 windows preferentially orientated to north in order to avoid the direct sunshine  
170 incidence on the samples. In this case, there are five windows in the northeast façade of  
171 the confined room, Figure 6.a.

172

173 Corn cob and expanded clay concrete samples were specifically produced for this test.  
174 These samples were sized 40 cm × 20 cm × 5 cm (width × height × thickness) as  
175 illustrated in Figure 3.b (detail II) for the corn cob concrete samples. Meanwhile, the  
176 XPS panel was 76 cm × 64 cm × 5 cm (width × height × thickness) (detail a, Figure  
177 6.b). The size of the XPS support panel (i.e. width and height) is similar to the size of  
178 the existing windows of the confined room. In this case, the windows identified as I and  
179 II in Figure 6 were used. A hole was done in the central part of the XPS panel with the  
180 same shape and dimensions of the samples. The corn cob (detail b, Figure 6.b) and the  
181 expanded clay (detail c, Figure 6.b) concrete samples were then placed in the hole of the  
182 XPS panel and both materials were connected by polyurethane foam. The set (i.e.  
183 sample and XPS) replaced a window and was also fixed by polyurethane foam, (detail  
184 d, Figure 6.b). All these experimental procedures require additional care in order to

185 avoid any undesirable insulation voids, thermal bridges, uninsulated headers and other  
186 faults which may compromise the feasibility of the final results.

187

#### 188 **4.2. Equipment and test preparation**

189 In this research work two heat transfer systems (i.e. one for each sample), two thermo  
190 hygrometric devices and a domestic heater device were adopted as the main equipment.  
191 Each heat transfer system included two heat flux measurement sensors (detail f, Figure  
192 6.b), four superficial temperature sensors (detail e, Figure 6.b), a data logger and a  
193 computer. The heat flux measurement sensors allow measuring the heat flow across a  
194 sample. A heat flow occurs when there is a significant thermal gradient between the two  
195 surfaces of a sample (i.e. indoor and outdoor surfaces). In this case, this gradient results  
196 from the existing thermal gradient between indoor and outdoor temperatures. The  
197 superficial temperature sensors were used as a complement and as reference of the heat  
198 flux measurement sensors, and in order to evaluate the inner surface temperature of the  
199 samples. It was adopted two superficial temperature sensors by heat flux measurement  
200 sensor and as Figure 6.b shows. One thermo hygrometric device was placed indoor and  
201 another one was placed outdoor. The heat transfer and the superficial temperature  
202 sensors were fixed on the inner face of the samples by adhesive tape, Figure 6.b. This  
203 procedure is extremely important taking into account the rugosity of the surface of the  
204 two tested samples types, which were corn cob concrete samples (ratio 6:1:1, aged 60  
205 days) and expanded clay concrete samples (ratio 6:1:1, aged 60 days). It is imperious to  
206 guaranty a perfect contact between the surfaces of the heat flux measurement sensor and  
207 the inner face of the samples, and to avoid any possibility of the sensors coming off  
208 during the test performance. According to [17], the test duration is related to the thermal  
209 inertia of the building component under study. For a high thermal inertia building

210 component a minimum of fourteen days test duration is recommended. On the other  
211 hand, for a low thermal inertia building component a minimum of 3 days of test  
212 duration is recommended. In this case, five days test duration was considered assuming  
213 that the both type of light weight concrete samples under study had low thermal inertia.

214

215 In the Portuguese context and, in particular, in the northeastern region of this country, it  
216 is convenient to perform this test during the winter or the summer because it is easy to  
217 assure the desirable uniform high thermal gradient between indoor and outdoor spaces.

218 A uniform high thermal gradient between indoor and outdoor is desirable because it  
219 corresponds to the ideal condition to allow a significant heat flow across the sample.

220 During the winter, this condition can be achieved by using a simple domestic heater  
221 device placed indoor and able to keep the room constantly warm. In contrast, during the  
222 summer, an air conditioner can be able to keep the room constantly cool. In this case,  
223 the test was performed during the winter, namely, in February of 2011. Therefore, a  
224 uniform high thermal gradient between indoor and outdoor was achieved by placing a  
225 common domestic heater device in the confined test room.

226

### 227 **4.3. Experimental results and discussion**

228 The two types of light weight concrete samples were tested in parallel. A continuously  
229 data acquisition was carried out during the test (in-between 10 minutes intervals (n)).

230 That acquired data comprised the values of the heat flow across the corn cob concrete  
231 sample ( $q'1(n)$  and  $q'2(n)$ , measured by the two used heat flux measurement sensors  
232 placed on this sample) and the values of the heat flow across the expanded clay concrete  
233 sample ( $q1(n)$  and  $q2(n)$ , measured by the two used heat flux measurement sensors  
234 placed on this sample). It also included the interior and the exterior temperatures ( $Ti(n)$

235 and  $T_e(n)$ ), and the relative humidity. Figure 7 depicts graphically the abovementioned  
 236 registered data.

237

238 In this case, it was necessary almost 48 hours ( $\Delta t$  stabilizing, Figure 7) to stabilize the  
 239 interior temperature at 20°C of the confined room. Meanwhile, the exterior temperature  
 240 had shown its natural and expected swing in a day time (e.g.  $\Delta T_{\text{night}}$  and  $\Delta T_{\text{day}}$ ,  
 241 Figure 7). For that period of the year, in the north region of Portugal, the exterior  
 242 temperature was always lower than the interior temperature. Therefore, adequate  
 243 thermal gradients were guaranteed (e.g. details I and II, Figure 7).

244

245 According to [17], the thermal transmission coefficient ( $U$ ) can be quantified by:

$$U(n_{total}) = \frac{\sum_{n=1}^{n_{total}} q(n)}{\sum_{n=1}^{n_{total}} (T_i(n) - T_e(n))} \quad (1)$$

246

247 where,  $U$  is the thermal transmission coefficient,  $q(n)$  is the heat flow across the sample  
 248 in the moment  $n$ ,  $T_i(n)$  and  $T_e(n)$  are the interior and the exterior temperature at the  
 249 moment  $n$ , respectively;  $n_{total}$  is the total number of moments in which the data was  
 250 registered.

251

252 Taking into account that two heat flux measurement sensors were used by each sample,  
 253 corresponding to  $q1(n)$  and  $q2(n)$ , it was possible to estimate two thermal transmission  
 254 coefficients for each sample,  $U1(n_{total})$  and  $U2(n_{total})$ , by applying Eq. 1. Thus, the  
 255 thermal transmission coefficient of each sample ( $U(n_{total})$ ) can be the average value of  
 256  $U1(n_{total})$  and  $U2(n_{total})$  and according to Eq. 2.

$$\dot{U}(ntotal) = \frac{U1(ntotal) + U2(ntotal)}{2} \quad (2)$$

257

258 Where,  $U(ntotal)$  is the thermal transmission coefficient of the sample,  $U1(ntotal)$  and  
 259  $U2(ntotal)$  is the thermal transmission coefficient related to the data registered by the  
 260 heat flux measurement sensor 1 and 2, respectively.

261

262 Based on the prior experimental data (Figure 7) and applying the previous expressions  
 263 the thermal transmission coefficient of each light weight concrete sample can be  
 264 estimated. These coefficients are presented in Table 4.

265

266 The results of Table 4 evidence the thermal insulation performance benefits of using  
 267 corn cob particles as an aggregate of lightweight concrete when comparing to a  
 268 lightweight concrete with expanded clay.

269

## 270 5. CONCLUSIONS

271 Granulate of corn cob, without containing any corn, is proposed as an alternative natural  
 272 aggregate of light weight concrete. Generally, corn cob is considered an agricultural  
 273 waste. Using it as an alternative to expanded clay, cork, EPS, among other possibilities  
 274 may have an interesting economic and sustainable benefit. At this stage, the obtained  
 275 experimental results indicate that corn cob concrete processed according to ratio of  
 276 6:1:1 (corn cob granulate:Portland cement:water) may have acceptable material  
 277 properties. For instance, the density and the thermal performance properties are in  
 278 accordance with the respective material properties of an expanded clay concrete.  
 279 However, the studied corn cob concrete has shown low compression strength when  
 280 compared to the expanded clay concrete. Aspects related to the granulometry of the corn

281 cob particles, the ratio of components and the curing time may justify the above  
282 vulnerability. Nevertheless for non-structural application purposes, such as pavement's  
283 regularization layers may be suitable. Further research will be carried out to solve the  
284 abovementioned low concrete strength.

356 **LIST OF TABLES**

357 Table 1 – Compression test results of the corn cob concrete samples (ratio 6:1:1)

358

359 Table 2 – Compression test results of the expanded clay concrete samples (ratio 6:1:1)

360

361 Table 3 – Compression test results of the corn cob concrete samples (ratio 3:1:1)

362

363 Table 4 – Thermal transmission coefficient ( $U^{\text{ntotal}}$ ) of the two lightweight concretes

364

365 Table 1: Compression test results of the corn cob concrete samples (ratio 6:1:1)

Sample	Mass (kg)	Density (kg/m <sup>3</sup> )	Ultimate load (kN)	Compression strength (kN/m <sup>2</sup> )
1	1.21	358.5	2.0	88.9
2	1.46	432.6	5.1	226.7
3	1.22	361.5	1.9	84.4
4	1.27	376.3	1.8	80.0
Average	1.29	382.2	2.7	120.0

366

367 Table 2: Compression test results of the expanded clay concrete samples (ratio 6:1:1)

Sample	Mass (kg)	Density (kg/m <sup>3</sup> )	Ultimate load (kN)	Compression strength (kN/m <sup>2</sup> )
1	2.04	604.4	38.7	1720.0
2	1.87	554.1	24.5	1088.9
3	1.86	551.1	24.0	1066.7
4	2.01	595.6	35.2	1564.4
Average	1.95	576.3	30.6	1360.0

368

369 Table 3: Compression test results of the corn cob concrete samples (ratio 3:1:1)

Sample	Mass (kg)	Density (kg/m <sup>3</sup> )	Ultimate load (kN)	Compression strength (kN/m <sup>2</sup> )
1	2.3	681.5	6.3	280.0
2	3.2	948.1	11.5	511.1
3	2.5	740.7	8.6	382.2
4	2.5	740.7	8.9	395.6
Average	2.6	777.8	8.8	392.2

370

371 Table 4: Thermal transmission coefficient ( $U_{total}$ ) of the two lightweight concretes

Sample	$U_{total}$ (W/m <sup>2</sup> °C)
Corn cob concrete	1.99
Expanded clay concrete	2.72

372

373 **LIST OF FIGURES**

374 Figure 1 – Examples of applications of regularization layer.

375

376 Figure 2 – Expanded clay vs Corn cob (without corn)

377

378 Figure 3 – Processing of the corn cob concrete samples for the compression test

379

380 Figure 4 – Processing of the expanded clay concrete samples for the compression test

381

382 Figure 5 – Compression test procedure

383

384 Figure 6 – Facility and sample setting up

385

386 Figure 7 – Interior ( $T_i(n)$ ) and exterior ( $T_e(n)$ ) temperatures. Heat flow across the corn  
387 cob ( $q_1(n)$  and  $q_2(n)$ ) and the expanded clay ( $q_1(n)$  and  $q_2(n)$ ) concrete samples.

a) Ground floor

b) Upper floor

c) Terrace

Key: 1 – Wood floor; 2 – Air layer; 3 – Regularization layer; 4 – Extruded polystyrene (XPS); 5 – Pavement; 6 – Plaster; 7 – Ceramic tiles; 8 - Pebble

Figure 1: Examples of applications of regularization layer

a) Corn cob (without corn)

b) Granulate of corn cob

c) Expanded clay

Figure 2: Expanded clay vs Corn cob (without corn)

389

390

391

a) Adding

b) Curing

c) Unmoulding

Figure 3: Processing of the corn cob concrete samples for the compression test

392

393

a) Adding

b) Curing

c) Unmoulding

Figure 4: Processing of the expanded clay concrete samples for the compression test

394

395

396

b) Corn cob concrete sample

c) Expanded clay concrete sample

Figure 5: Compression test procedure

397

398

a) Confined room (m)

b) Set up

Key: a – XPS; b – Corn cob concrete sample; c – Expanded clay concrete sample; d - Polyurethane foam; e - Superficial temperature sensor; f - Heat flux sensor

Figure 6: Facility and sample setting up

399

400

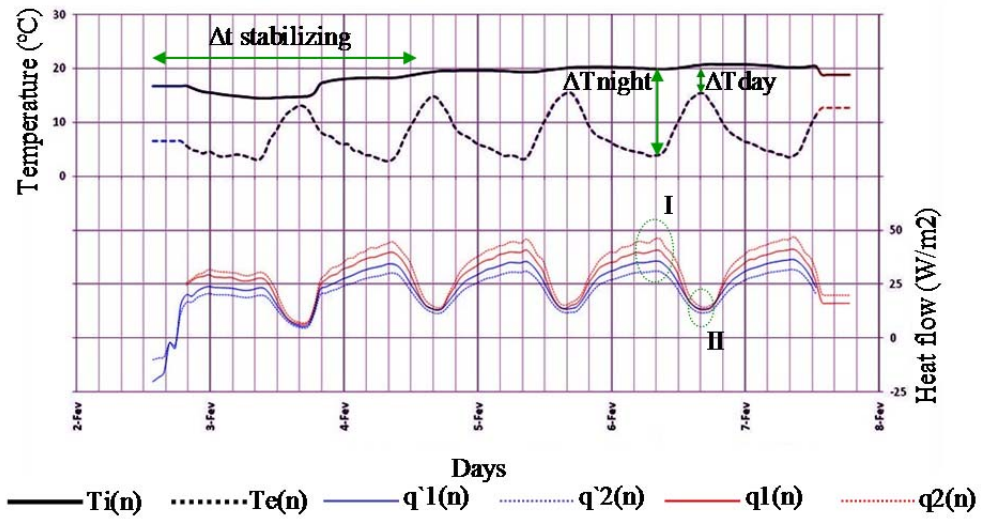

Figure 7: Interior ( $T_i(n)$ ) and exterior ( $T_e(n)$ ) temperatures. Heat flow across the corn cob ( $q'1(n)$  and  $q'2(n)$ ) and the expanded clay ( $q1(n)$  and  $q2(n)$ ) concrete samples. February (Fev) of 2011
