Abstract:
Purpose: This study was carried out to create a research model investigating the impact of supply chain quality management (SCQM) practices on firm performance.

Design/methodology/approach: Based on a comprehensive literature review, the practices were suggested. These SCQM practices will be analyzed and categorized into 4 dimensions: upstream (supplier assessment, supplier quality management), downstream sides of a supply chain (customer focus), internal process (product/service design, process management and logistics) and support practices (top management support, human resource management, information and supply chain integration). The measurement instrument of firm performance was developed including three aspects: operational performance, customer satisfaction and financial performance.

Findings: A conceptual framework and a structural model were proposed as well as the development of hypotheses on the paths.

Research limitations/implications: It is necessary to test the rationality of this model by empirical studies in different contexts.

Originality/value: The research considers integration of quality and supply chain management still remains limited in the literature. Therefore, it is necessary to have a more focused approach in assessing quality management issues within the internal and external supply chain contexts. This study concentrates on the practices which improve quality aspects of supply chain, known as SCQM practices. Proposed structural model in this paper not only fills the voids in the literature but contributes a parsimonious conceptual framework for theory building in SCQM and firm performance. It also expects to offer a useful guidance for measuring and implementing SCQM practices as well as facilitate further studies in this field.

Keywords: Quality management, Supply chain management, Supply chain quality management practices, firm performance.

Article Classification: Conceptual paper
1. Introduction

As competition moves beyond a single firm into the supply chain, organizations began to realize that it is not enough, if they only pay attention to improve performance within their own company. According to Li et al. (2006), the development and implementation of Supply chain management (SCM) can maximize customer value and gaining a competitive advantage in the marketplace and getting a good profit as well. Thus, SCM becomes increasingly important.

The concept of SCM has attracted the attention from academicians and business managers. Many organizations have started recognizing that SCM is the main factor to create a sustainable competitive edge for their products and/or services in an increasingly crowded marketplace.

In supply chain, quality plays an important role. Establishment of a quality-based culture can improve operational performance, customer satisfaction, financial performance, etc. along the supply chain (Kaynak and Hartley, 2008).

Several researchers have suggested to integrate quality and supply chain management. However, this implementation still remains limited (Robinson and Malhotra, 2005). Therefore, it is necessary to have a more focused approach in assessing quality management issues within the internal and external supply chain contexts.

This study will concentrate on the practices which improve quality aspects of supply chain, known as supply chain quality management (SCQM) practices. Also, a structural model will be proposed to investigate the relationship between SCQM practices and performance.

Examining these relationships is very important because it allows us to understand deeply how SCQM practices impact on performance in supply chain. And this study also expects to offer the useful guidance for measuring and implementing SCQM practices as well as facilitate further researches in this field.

The structure of this paper is as follows: the next section is literature review that previous studies concerning SCQM are documented. In section 3, the SCQM practices and firm performance were described. Then, research model and hypotheses are suggested. Implications and directions for further research are mentioned at the end of this paper.

2. Literature review

This section is separated into 2 parts. Firstly, various definitions of SCQM are documented. Then, an appropriated one is suggested. Next, empirical studies are reviewed to explore research gaps in the literature.

2.1 Definitions of SCQM

There are some previous studies to define SCQM in different perspectives. According to Ross (1998), it is the participation of all members in a supply chain to improve all processes, products, services, and work cultures, etc. It will result in increasing productivity, competiveness and customer satisfaction.

Kuei et al. (2001) defined SCQM in the three following equations:

1. SC = a suppliers – manufacturers – customers network;
2. Q = meeting market demands correctly, and improving operational performance, customer satisfaction, financial performance; and
3. M = facilitating, encouraging the quality processes and activities, increasing trust for supply chain quality.

SCQM is the coordination, integration and optimization of quality activities among members in a supply chain. It manages product quality and processes effectively in order to gain competitive advantage, customer satisfaction and market share (Robinson and Malhotra, 2005).

SCQM is an SCM extension that is designed to help firms to establish a competitive supply chain through application of quality management practices (Kuei et al., 2008).
In sum, SCQM is the orientation, coordination and implementation of all activities taking place in supply chain smoothly. It is helpful to improve operational quality and product quality as well as to increase customer satisfaction.

2.2 Research gaps

There are some empirical studies to investigate the impact of SCQM on firm performance. However, they still remain some limitations that need to further explore. Based on extensive literature review, the research gaps are indicated, including:

- Lack of a research model covers upstream, internal process and downstream activities.
- Role of information has not yet fully examined.
- The inconsistency is in results of previous studies.
- The mutual interaction among practices has not been taken into account.
- Various dimensions of firm performance have not yet evaluated simultaneously.

For more detail, these research gaps will be discussed as follows.

SCQM has a significant impact on firm performance throughout practices along the entire supply chain that cover upstream, internal process and downstream activities (Kaynak and Hartley, 2008). It, however, has not been sufficiently examined in the literature. Some of previous studies focused only on the upstream side of the supply chain (Akamp and Müller, 2013; Hollos et al., 2011; Kumar et al., 2014; Wu et al., 2010). While others investigated the impact of downstream on performance (Danese and Romano, 2011; Mokhtar, 2013; Mukerjee, 2013). Vachon and Klassen (2006) examined integration between upstream and downstream. Conversely, other authors tested effects of internal process on performance (Adam et al., 1997; Ahire and Dreyfus, 2000; Ahire and O'Shaughnessy, 1998; Anderson et al., 1995; Choi and Eboch, 1998; Powell, 1995; Samson and Terziovski, 1999; Saraph et al., 1989). In sum, each study showed some different perspectives in a wide picture about relationship between SCQM practices and firm performance.

According to Kaynak and Hartley (2008), the implementation of SCQM is not only internal practices, which are contained within an organization, but external practices, which cross organizational boundaries integrating a company with its customers and suppliers, are also examined (figure 1).

![Figure 1: Internal and External Supply Chain](image)

In the study of Romano and Vinelli (2001), performance of two different supply chains in garment industry was investigated. One is a traditional chain with no formal integration, and the other has involvement of upstream and downstream partners in activities of the focal firm. The study found that the supply chain which has integration and cooperation among members is better able to meet expectations of customers.

On the other hand, for this successful integration, information plays an extremely important role (Ding et al., 2014; Inderfurth et al., 2013; Qrunfleh and Tarafdar, 2014; Wu et al., 2014; Zhou et al., 2014). Lack of information or distorted information passed from one end of the supply chain to the other, can create significant problems, including, but not limited to, excessive inventory investment, poor customer...
service, lost revenues, misguided capacity plans, ineffective transportation, and missed production schedules. These are not deliberate attempts to sabotage the performance of fellow supply chain members. Rather, distorted information throughout the supply chain will result in bullwhip effect (Handfield and Nichols, 2008). A further study which covers four major dimensions of SCQM including: internal process, upstream, downstream and information is essential to provide more macro guidance for quality integration in whole supply chain network.

Additionally, in QM or SCM literature, the results of previous studies are inconsistent in order to consolidate the statement of the influence of SCQM practices on firm performance (Kaynak and Hartley, 2008). For instance, in the relationship between customer focus and performance, the direct impact of customer focus on performance is supported by Prajogo and Brown (2004), Feng et al. (2006), Fening et al. (2008), Terziovski (2006), Samson and Terziovski (1999), Lakhal et al. (2006), Dow et al. (1999). However, according to Tari et al. (2007), Zu (2009), Su et al. (2008), customer focus indirectly effects on performance through the relationship with other practices. Also, Rahman and Bullock (2005) pointed out that there are indirect and direct relationship between them. Otherwise, between process management and performance, the direct influence of process management on performance have been identified in several studies (Feng et al., 2006; Fening et al., 2008; Kaynak, 2003; Kaynak and Hartley, 2008; Prajogo and Brown, 2004; Sila and Ebrahimpour, 2005; Terziovski, 2006; Zu, 2009). However, Tari et al. (2007) argued that they have an indirect relationship. Conversely, Flynn et al. (1995) proved that process management has negative direct impact on performance, or even they are not associated as the studies of Powell (1995), Samson and Terziovski (1999).

Also, it is more important that these investigations are mainly to concentrate on the directly relationships, there is a lack of examining interactions among SCQM practices (Dow et al., 1999). According to Kaynak (2003), it is not comprehensive if a research model does not show relationship among practices. In other words, further studies need to identify the direct and indirect impact of SCQM practices on firm performance at multiple levels.

So far, few studies have considered the effect of SCQM practices on various dimensions of firm performance. Most of them are to focus on the relationships between SCQM practices and a single performance measure, such as: financial performance (Li et al., 2006), operational performance (Bayraktar et al., 2009; Devaraj et al., 2007; Fawcett et al., 2007; Wong et al., 2011), supplier/buyer performance (Shin et al., 2000), customer satisfaction (Power et al., 2001), etc.

It is hoped that by addressing diversified aspects of SCQM practices simultaneously as well as examining the direct and indirect impact of these practices on various firm performance, this study will provide a parsimonious conceptual framework for theory building in SCQM and firm performance.

3. Identification of SCQM practices and firm performance

3.1 Methodology

SCQM practices were documented based on extensive literature review in both areas of QM and SCM. Then, they were divided into four groups: upstream, internal process, downstream and support practices. The next step was to refine these practices that the similar ones were deleted. It is hope that the remaining practices will cover four above aspects.

Traditionally, firm performance was primarily evaluated by financial indicators such as sales revenue, market share, return on investment or return on sale. (Li et al., 2006). It is not comprehensive because firm performance is also reflected by other goals. In 1993, Kaplan and Norton introduced balanced scorecard including four different perspectives of performance indicators: financial, customer, internal processes and innovation and learning. Based on them, the measurement scales for firm performance were designed.
3.2 SCQM practices

As discussed, a comprehensive implementation of SCQM needs to cover four major dimensions including: upstream, internal process, downstream and information.

Based on an extensive literature review, the most relevant SCQM practices are identified (see Table 1). The classification adopted in this study (Flynn et al., 1995) assumes three main categories:

- **Upstream**: supplier management consists of supplier assessment and supplier quality management.
- **Downstream**: customer focus.
- **Internal process**: product/service design, process management and logistics.

Moreover, to ensure that activities in the entire supply chain are performed smoothly, the practices of human resource management, top management support, supply chain integration and information, known as support practices, are suggested.

### Table 1: Description of SCQM practices.

an extensive structural model of supply chain quality management and firm performance

An extensive structural model of supply chain quality management and firm performance. (Vanichchinchar and Igel, 2010)

**Information Sharing**

- Share of proprietary information. Announcement about issues affecting company's business. Share of business knowledge about core business processes. Information exchange to establish business planning. Announcement about events or changes. Face-to-face planning/communication. (Li and Lin, 2006; Li et al., 2006; Li et al., 2005)

**Information Quality**

**Information Management**

- Data collection about trade partners' activities. A common standard for information sharing. Evaluation of formal and informal complaints and satisfaction. Information sharing among functions. Important information transmission to employees. Use of information to improve key processes, products and services. (Vanichchinchar and Igel, 2010)

**Information Technology**

- Direct computer-to-computer links. Inter-organizational coordination based on electronic links. Use of information technology-enabled transaction processing. Electronic mailing capabilities. Use of electronic transfer of purchase orders, invoices, and/or funds. Use of advanced information systems to track and/or expedite shipments. (Prajogo et al., 2012)

### 3.3 Firm Performance

Firm performance is defined as how a firm achieves its market goals, and also its overall goals (Yamin et al., 1999). This study defines the set of measures for firm performance according to the four dimensions of balance scorecard. In which, financial perspective is measured by financial performance, customer satisfaction represents for customer perspective and finally, operational performance consists of internal processes, innovation and learning. Detail description of each dimension is in table 2.

<table>
<thead>

<td>Response to customer standards. Customer evaluation to firm performance. Continuity to use firm’s product/service. Recommendation of firm’s product/service to others. (Bozarth et al., 2009; Taylor and Baker, 1994)</td>
</tr>
</tbody>
</table>

From above, the conceptual framework is suggested in Figure2.
An extensive structural model of supply chain quality management and firm performance

Figure 2: Conceptual framework
4. Structural model and hypotheses

From literature review, we can see that previous studies suffered incomplete consideration of SCQM dimensions as well as insufficient examination of the direct and indirect impact of these practices on various firm performance. This study will try to fill this void by proposing a comprehensive framework covering all suggested dimensions and developing related hypotheses as follows.

![Figure 3: Structural model](image)

Figure 3 describes the proposed structural model. In this model, internal process, supplier management and information are presented as second-order latent constructs. The structural relationships are depicted by arrows and will be discussed as follows.

4.1. Top management support

The support of top management is the main motivation that drives companies towards an effective and successful implementation of SCQM (Abraham et al., 1999; Ahire and Dreyfus, 2000; Ahire and O'Shaughnessy, 1998).

In any companies, customer satisfaction is the key driver of all activities. Therefore, customers’ needs must be properly addressed not only by top managers but all employees also (Lakhal et al., 2006). Top management support is essential in ensuring that necessary resources are provided to carry out market studies to determine customers’ needs and wants as well as making all efforts to meet them (Kaynak, 2003).

Additionally, in the SCM perspective, customer involvement in firm’s activities plays an important role in the success of the whole supply chain (Robinson and Malhotra, 2005). Top management can promote customer involvement from the earlier stages of development until the commercialization stage (Flynn et al., 1995). Top management, further to define companies’ mission and goals, creates the working environment in which all employees are encouraged to focus on addressing customer requirements (Ahire and Ravichandran, 2001).

As traditional approaches, supplier management is seen as a mere administrative activity that mainly focuses on supplier selection. In this activity, price is the main criterion to evaluate suppliers. This can result in poor quality materials or even delayed orders. In new perspective, supplier management refers
not only to the selection of quality suppliers, but to the development of long-term relationship with suppliers and assessment of suppliers’ performance also (Li et al., 2005). However, to ensure that this implementation is successful, it is necessary to have support from top management (Kaynak, 2003; Kaynak and Hartley, 2008; Sila and Ebrahimpour, 2005; Singh, 2008; Zu et al., 2008). Top management actively participates in this process and selection will be based on review of more demanding criteria, e.g. quality, reliability in delivery activities and service. It ensures that firm has a reliable and high quality suppliers (Flynn et al., 1995; Trent and Monczka, 1999). Moreover, effective supplier management is considered as a strategic area by top managers promoting higher levels of integration and collaboration (e.g. design, production, marketing, sales and customer service) with key suppliers. Thereby, communication, relationship, and cooperation among parties in the supply chain are improved (Ellram, 1995). Hence, we propose the following hypotheses:

**H1a: Top management support positively impacts on customer focus.**

**H1b: Top management support positively impacts on supplier management.**

**H1c: Top management support positively impacts on supply chain integration.**

Top management creates an environment conducive to the development of all employees and promotes the motivation of employees. By empowering, employees could make their own decisions in their tasks. Top management, moreover, supports employees to involve in determining training needs and have training program to improve quality-related skills and knowledge for employees. There are some studies that found a positive relation of top management support to human resource management (Kaynak and Hartley, 2008; Ou et al., 2010; Sila and Ebrahimpour, 2005; Singh, 2008; Tari et al., 2007). Hence, the following hypothesis is proposed:

**H1d: Top management support positively impacts on human resource management.**

To operate a supply chain smoothly, information needs to be shared among partners. However, this leads to a concern that information disclosure is as a loss of power (Mason-Jones and Towill, 1997). Thus, to ensure that information practice is applied successfully, top management support has a significant role. They are those who can decide types of shared information and extent to which critical and proprietary information is communicated to supply chain partners as well as transmitted to employees within their company. Moreover, the accuracy, timeliness, adequacy, and credibility of information exchanged are also determined by top management. Furthermore, top management makes decisions to invest necessary facilities to apply information technologies in daily activities. Hence, we suggest the following hypothesis:

**H1e: Top management support positively impacts on information.**

### 4.2. Customer focus

Customer focus is considered as a key element for successful enterprises. All activities such as the development of new product/services, production, marketing, distribution and after-sales services should be concentrated on customer requirements. Each department and every employee should share customer-focused vision alike (Ahire and O’Shaughnessy, 1998; Ahire and Ravichandran, 2001; Flynn et al., 1995; Forza and Filippini, 1998; Lakhal et al., 2006; Nair, 2006; Sila and Ebrahimpour, 2005).

The implementation of customer focus practice helps companies to better understand customer expectations and market opportunities (Lakhal et al., 2006). Based on them, firms can be active in planning for design, purchasing, production, delivery, etc. For instance, firms can balance supply and demand, reducing variance in processes (Lee et al., 1997). In production activities, by understanding customer’s demand, company can coordinate effectively machines, equipment and human resources to minimize process complexity and variance.
Furthermore, employees know attributes of products/services which bring benefits for customers can enhance the efficiency of their jobs. As a result, errors are minimized as well as improvements in design, production, delivery, etc., are also suggested. Moreover, since customer’s needs and wants are determined, firms concentrate their efforts on responding them. It is helpful to increase productivity of internal process (Dow et al., 1999; Fening et al., 2008; Lakhal et al., 2006; Rahman and Bullock, 2005; Samson and Terzirovski, 1999; Zehir and Sadikoglu, 2010). Hence, the following hypothesis is proposed:

**H2: Customer focus positively impacts on internal process.**

### 4.3. Supplier Management

The successful implementation of supplier management ensures that input materials meet standards and quality requirements in order to produce quality products (Chen and Paulraj, 2004; Kaynak, 2003; Kaynak and Hartley, 2008; Li et al., 2005; Ou et al., 2010; Robinson and Malhotra, 2005; Vickery et al., 2003). High quality inputs, provided at the right time with the required quantity, helps firm to avoid downtime incidents, to reduce variance in processes and the rate of damaged materials (Flynn et al., 1995; Forza and Filippini, 1998). Moreover, effective supplier management can cut off inventory, waste and safety inventory level (Easton and Jarrell, 1998; Yeung, 2008). Hence, we suggest the following hypotheses:

**H3. Supplier management positively impacts on internal process.**

### 4.4. Supply chain integration

From a supply chain perspective, integration of trade partners in firm’s activities can increase the efficiency of internal process (Robinson and Malhotra, 2005). For instance, suppliers can offer the most appropriated components or parts for designing new products (Hoegl and Wagner, 2005), and help purchasers buy inputs that can be used most efficiently in manufacturing processes and delivery (Flynn et al., 1995; Forza and Filippini, 1998; Shin et al., 2000; Tan, 2001; Trent and Monczka, 1999).

In another perspective, by participation on cross-functional design teams, contribution of new ideas, selection of ideas and features for further product/service development or choosing components for new products, etc., customer involvement directly increases the effectiveness of product/service design (Ulwick and Teitelbaum, 2005). In activities of production and distribution, moreover, suggestions of customer is a base to identify underlying issues.

Furthermore, Flynn et al. (2010) proved that share of knowledge about core business processes among members in supply chain improves the operations in internal process of each firm. Hence, the following hypothesis is offered:

**H4. Supply chain integration positively impacts on internal process.**

### 4.5. Human resource management

Human resource is considered as the most important resource in any firms, it is also a key factor deciding the success of companies. This is right even when a company has good technologies and equipment. Because all activities in a firm always require human interaction (APO, 2000). Human resource management refers to create a good environment for employees that they are trained and empowered to implement their tasks (Adam, 1994; Choi and Eboch, 1998; Park et al., 2001; Powell, 1995; Samson and Terzirovski, 1999).

Employees are those who transfer market and consumer needs into designs. Quality-related training programs ensure that employees have knowledge and skills to design products/services as required. In addition, it also helps employees know how to use quality improvement tools, such as, statistical techniques, fool-proofing for process design, etc. in their daily tasks (Ahire and Dreyfus, 2000; Ho et al., 1999). Employees could reduce unnecessary or excess motions and process complexity (Sila and
Ebrahimpour, 2005; Tari et al., 2007; Zu et al., 2008). Moreover, empowerment allows employees actively suggest innovations at their plant. Hence, we suggest the following hypothesis:

**H5. Human resource management positively impacts on internal process.**

### 4.6. Information

For integration of members within the supply chain, information systems plays an important role (Zhao et al., 2002). According to Stein and Sweat (1998), supply chain partners who exchange information regularly are able to work as a single entity. Together, they can understand the needs of the end customer better and hence, can respond to market change quicker. Many researchers have suggested that the key to the seamless supply chain is making available undistorted and up-to-date marketing data at every node within the supply chain (Childerhouse and Towill, 2003). Moreover, by taking the data available and sharing it with other parties within the supply chain, the negative impact of the bullwhip effect on a supply chain can be also reduced or eliminated (Yu et al., 2001). On the other hand, Bayraktar et al. (2009) argued that relevant information is transmitted timely to employees can improve efficiency of internal activities.

With the growing popularity of e-business and e-supply chain, information technology is a crucial factor in a successful organization and its supply chain. By using direct computer-to-computer links, electronic links or electronic mailing capabilities, etc., information technology can increase communication among members in supply chain network as well as departments in a firm. Effectiveness of internal process is also enhanced by applications of advanced information systems in transaction processing, electronic transfer of purchase orders, invoices, funds or track and expedite shipments (Prajogo et al., 2012). Hence, we proposed the following hypotheses:

**H6b. Information positively impacts on supply chain integration.**

**H6b. Information positively impacts on internal process.**

### 4.7. Internal process

Internal process refers to all activities in a firm. This concept, therefore, is considered as a second-order latent construct including 3 practices: product/service design, process management and logistics. The successful implementation of internal process throughout these practices has a significant impact on operational performance.

Product/service design refers to simplify products, reduce component parts per product and increase the level in the use of standard components (Chase et al., 2006; Kannan and Tan, 2005). Reduction of component parts per product and high level of standardization make employee’s tasks easier. They quickly get acquainted with their works that makes low rate of errors, lead-time is shorter and output is increased (Tan, 2001). The cost of repair and rework is also significantly reduced (Ahire and Dreyfus, 2000; Anderson et al., 1995). Moreover, simple components and products make delivery easier. As a result, rate of late delivery is decreased.

Process management refers the use of statistical techniques, increasing automatic level of processes and fool-proof in designing process (Flynn et al., 1995; Forker, 1997; Kaynak, 2003; Saraph et al., 1989). These activities are helpful in decreasing process variance (Flynn et al., 1995) and minimizing chances of employee errors (Forker, 1997; Kaynak, 2003; Saraph et al., 1989). Consequently, output increases and uniformity of products is higher (Anderson et al., 1994; Forza and Filippini, 1998). Furthermore, the use of preventive equipment maintenance make manufacturing process smoothly by improving reliability of equipment and restricting disruption in production (Ho et al., 1999). The relation of process management to operational performance is founded in the studies of Ahire and Dreyfus (2000); Forza and Filippini (1998).

One of logistics implementation refers to select facility location close to suppliers and customers as well as modify order size (Stank et al., 2001). It ensures that distribution activities are fast and more
effective. As a consequence, rate of late delivery and damaged materials in transportation are minimized (Kenneth et al., 2008). All above, the following hypothesis is recommended:

**H7. Internal process positively impacts on operational performance.**

### 4.8 Firm performance

Operational performance refers to the ability of a company in reducing management costs, order-time, lead-time, improving effectiveness of using raw material and distribution capacity (Heizer et al., 2008). Kaynak (2003) indicated that a high operational performance firm is able to produce quality products/services that increase customer satisfaction (Choi and Eboch, 1998; Ou et al., 2010), revenue and profit for companies (Ahire and Dreyfus, 2000; Kaynak, 2003; Kaynak and Hartley, 2008; Yeung, 2008).

Furthermore, since unnecessary costs are reduced, firms are able to offer lower prices for their products/services. Consequently, market share and sales revenue are also increased (Maani et al., 1994). Moreover, improving efficiency in the use of machines, equipment, warehouses, etc. will increase return on assets (Kaynak, 2003). Otherwise, as a firm has ability to offer high quality products/services, higher price can be charged, which, can increase return on sales (Kaynak, 2003). Last but not least, a high quality product/service offered at the low price will make customer more satisfied (Choi and Eboch, 1998). Hence, two following hypotheses are proposed:

**H8a. Operational performance positively impacts on customer satisfaction.**

**H8b. Operational performance positively impacts on financial performance.**

According to Buchanan and Gillies (1990), customers who are content with products/services of a company are less likely to switch to competitors, thereby, market share is maintained. Moreover, they tend to be less price sensitive or even willing to pay at a higher price, this can result in increasing sales and return on sales. Likewise, a satisfied customer will introduce to other potential customers. As a consequence, market share is increased.

**H8c. Customer satisfaction positively impacts on financial performance.**

### 5. Conclusion

This paper proposed a structural model to consider the integration between quality and supply chain management which is still limited in the literature. Based on extensive literature review, the research gaps in previous studies were indicated. Those are: (i) lack of integration among internal process, upstream and downstream side of SCQM, (ii) role of information in this integration is not emphasized, (iii) insufficient examination of various dimensions of firm performance and (iv) the causative links among SCQM practices. These things lead to detract from benefits of the SCQM implementation in previous results (Li et al., 2006).

Proposed structural model in this study not only fills the above voids but contributes a parsimonious conceptual framework for theory building in SCQM and firm performance. It covers diversified aspects of SCQM practices and firm performance as well as presents the direct and indirect effects of these practices on various firm performance simultaneously. Investigating these relationships is very important because it allows us to understand deeply how SCQM practices impact on performance in supply chain. And we also expects that research models suggested in this paper can offer a useful guidance for measuring and implementing SCQM practices as well as facilitate further studies in this field. For future researches directions, it is necessary to test the rationality of these models by empirical studies in different contexts.
