Abstract. The recent and massive investments in Electric Vehicles (EVs) reveal a change of paradigm in the transports sector and the proliferation of EVs will contribute to an effective reduction in the emissions of greenhouse gases. Nevertheless, for the electrical power grids EVs will be extra loads, which will require the demand energy to charge their batteries. With the advent of the Smart Grids, besides the usual battery charging mode (Grid-to-Vehicle – G2V), where the batteries receives energy from the power grid, arises a new concept for the users of EVs and for the power grid market, denominated as Vehicle-to-Grid (V2G). In the V2G operation mode, EVs return to the power grid part of the energy stored in their batteries. The V2G concept requires the use of battery chargers for the EVs with bidirectional power flow capability and bidirectional communication with the Smart Grids through Information and Communication Technology (ICT) applications. It is important to highlight that the proliferation of EVs and the impact of their battery chargers on the power grid quality is a matter of concern, since conventional chargers present current harmonics and power factor problems. In this paper it is presented the preliminary studies resulting from a PhD work about a bidirectional battery charger for EVs, which was designed to operate in collaboration with the power grid as G2V and V2G through an ICT application. In this way, it is expectable to contribute to the technological innovation of the electric mobility in Smart Grids. To assess the behavior of the proposed battery charger under different scenarios of operation, a prototype has been developed, and some simulation and experimental results of the battery charger are presented.

Keywords: Battery Charger, Communication System, Electric Vehicles, Smart Grids, Grid-to-Vehicle (G2V), Vehicle-to-Grid (V2G)

1   Introduction

The upcoming reality of Smart Grids and energy markets will raise a diversity of advantages to the end-user. However, it will require several technologic developments aiming the interaction of the users as active players. The recent increase in the utiliza-

tion of Electric Vehicles (EVs) with different architectures represents a real contribution to a new transports paradigm, a gain for independence of the cost of the oil, and also an effective fight against the climatic changes. Effectively, the EVs are seen as one of the most promising means in order to improve the sustainability of the transportation and energy sectors in near-term [1][2].

The EVs in conjunction with Information and Communication Technology (ICT) applications will play an important role to achieve a sustainable balance between production and consumption, and increase the power quality and the reliability of the power grids. The future Smart Grids are the consequence of this new paradigm for the power grids. Smart Grids are not characterized as a particular technology or device, but rather as a vision of a distributed electrical system, supported by reference technologies, as example, the aforementioned ICT, Advanced Metering Infrastructures (AMI), Energy Storage Systems (ESS), Micro Generation (MG), and Power Electronics Systems (PES). Thereby, the actual power grids will be transformed on a coordinated, collaborative [3], and automatic infrastructure [4][5][6].

Nowadays, with the recent bet in EVs around the world, the actual electrical power grids are facing new challenges, forcing to a wide efforts of investigation in different directions [7], mainly taking into account their integration [8][9][10]. Consequently, a considerable amount of energy is stored in the batteries of these vehicles. Thus, besides the charging process (Grid-to-Vehicle – G2V), the energy stored in EVs' batteries may be suitable for providing regulation services, spinning reserves and peak power demand. This interactivity between the vehicles and the power grid is expected to be one of the key technologies in the future of the Smart Grids, denominated Vehicle-to-Grid (V2G) [11][12]. Fig. 1 shows a draft of a scenario for a Smart Grid, where the integration of EVs represents the core of the context for this paper.
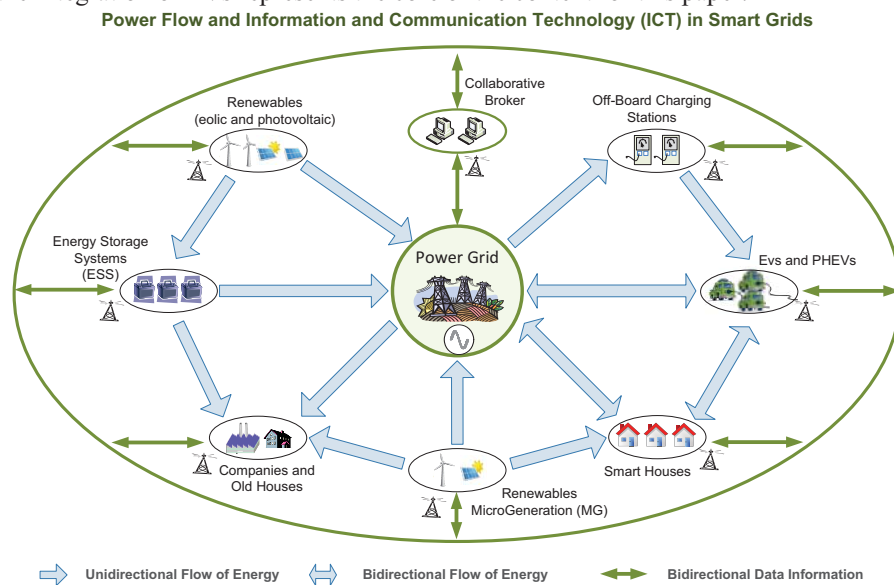

Fig. 1. Scenario for a Smart Grid, where the integration of EVs with bidirectional power flow and communication capabilities represents the core of the context for this paper.

This paper results from a PhD work that is yet in the first year, and presents a bidirectional battery charger for EVs based on PES with ICT capabilities. This equipment allows mitigate problems associated with power quality (as distorted current consumption and low power factor), enables the operation of EVs as local ESS, and represents an important contribute to the technological innovation, and to the efficiency and reliability of the electric mobility in Smart Grids.

2 Contribution to Internet of Thinks

The Functional Areas in Smart Grids represents all the systems related with the production, transmission and distribution [13][14], and considering Advanced Metering Infrastructure (AMI) and ICT [15][16]. In the electric mobility it is important provide the EVs with ICT systems in order to establish a bidirectional flux of information to ensure that the batteries are charged when the electricity is cheapest and the impact on the grid is smallest. With a coordinated charging process of EVs the energy losses in the distribution system are minimized [17]. To reach this goal, the batteries charging process needs assistance of an intelligent process in order to find the periods with cheaper prices to charge the batteries, to identify the available charging slots in public and private areas, and to provide other useful information to the drivers, as their historic use [18][19]. This theme, including supervision, control and communication applications, will be the final topic that will be addressed in the PhD work. The main goal is establish a bidirectional flux of information between the EVs and the power grids aiming to define strategies of cooperation to the G2V and V2G modes of operation [20].

In order to contribute to the technological innovation of the electric mobility in Smart Grids, the bidirectional battery charger for EVs presented in this paper was designed to operate in collaboration with the power grid as G2V and V2G through an ICT application [21]. This way, it will be possible exchange information through the internet, contributing to strengthening the Internet of Things and the impact of the electric mobility in the Smart Grids. As aforementioned, besides the bidirectional flow of active power, through the power factor control, it is also possible control the reactive power in accordance with the capabilities of the battery charger [22]. In Fig. 2 is shown the integration of EVs in the power grid considering the active and reactive bidirectional power flow of the presented battery charger.

Fig. 2. Smart Grid considering the integration of EVs with bidirectional power flow.

3 On-Board Battery Charger

Electric Vehicles are becoming a part of the electric power grid and consequently the battery chargers of these vehicles should have the ability to avoid power quality problems [23][24]. Even more, the EVs power stages can also assume, if needed, the role of the active power quality filters. The battery charger presented in this paper is a device that is composed by two power electronics converters used to adapt the AC electrical energy into DC (AC-DC converter) and to control the output voltage or currents levels (DC-DC converter). To contribute to the power quality in the future Smart Grids, the battery chargers should consume sinusoidal current with controlled power factor. In Fig. 3 is presented the schematic of the first prototype of battery charger developed during the PhD work.

Fig. 3. Schematic of the presented bidirectional power converter.

3.1 Modes of Operation

In an early stage, in order to analyses the operation of the converters in both modes of operation was developed a simulation model using the simulation tool PSIM, and were realized different computer simulations. In Fig. 4 are shown some simulations results obtained during the operation of the bidirectional power converters.

Fig. 4. Summary of some simulation results considering the voltage and the current in the electrical power grid and adjusting the reactive power.

3.2   Digital Control System

In a first stage of the PhD work, in this prototype, the operation of the battery charger occur in accordance with the orders given, according to the demands of the user of the EV, which define when it works as G2V and V2G, and the value of reactive power to be produced. The communication with the power grid through an ICT application, instead the user, will be developed along the PhD work where this paper is encompassed. In Fig. 5 are presented the control algorithms for the AC-DC and DC-DC converters.

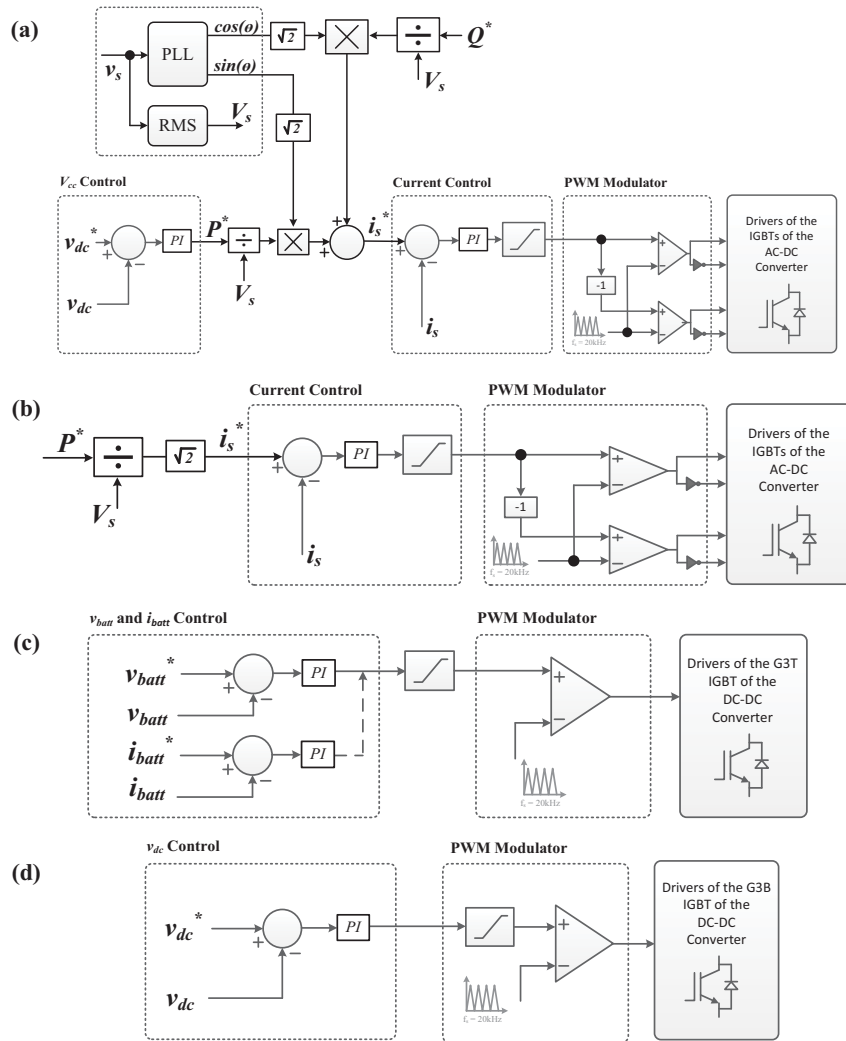

Fig. 5. Control algorithms: AC-DC converter operating as G2V (a) and V2G (b); DC-DC converter operating as G2V (c) and V2G (d).

4   Experimental Results

In order to assess the operation of the on-board battery charger under different modes of operation was developed the prototype presented in Fig. 6 aiming to be integrated in an EV with Absorbed Glass Mat batteries with nominal voltage 96 V and nominal capacity 33 Ah. Preliminary experimental results are shown in Fig. 7.

(a) G2V mode with unitary power factor; (b) V2G mode;
(c) G2V mode with capacitive power factor; (d) G2V mode with inductive power factor.

5   Conclusions and Further Work

In this paper was presented an on-board battery charger for Electric Vehicles (EVs) aiming their integration in Smart Grids. This battery charger allows the interaction with the electrical power grid to charge the batteries (Grid-to-Vehicle - G2V mode), or to deliver part of the stored energy in the batteries back to the power grid (Vehicle-to-Grid - V2G mode). The modes of operation and the reactive power control are performed considering the user interface of the EVs. However, in the final of the PhD work where this paper is encompassed, the goal is to control the on-board battery charger of the EV through an ICT application aiming to allow the communication with a collaborative broker of the electrical power grid.

In a first stage, the behavior of the bidirectional power converter was evaluated under different scenarios through computer simulations. Then the behavior of the bidirectional power converter was evaluated with a prototype, which was developed aiming to reduce its volume and weight, in order to be integrated in an Electric Vehicle with Absorbed Glass Mat (AGM) batteries. In this paper were presented the simulations and experimental results obtained.
