**Search for Quantum Black Hole Production in
High-Invariant-Mass Lepton+Jet Final States Using pp
Collisions at $\sqrt{s} = 8 \text{ TeV}$ and the ATLAS Detector**

The ATLAS Collaboration

Abstract

This Letter presents a search for quantum black-hole production using 20.3 fb^{-1} of data collected with the ATLAS detector in pp collisions at the LHC at $\sqrt{s} = 8 \text{ TeV}$. The quantum black holes are assumed to decay into a final state characterized by a lepton (electron or muon) and a jet. In either channel, no event with a lepton+jet invariant mass of 3.5 TeV or more is observed, consistent with the expected background. Limits are set on the product of cross sections and branching fractions for the lepton+jet final states of quantum black holes produced in a search region for invariant masses above 1 TeV . The combined 95% confidence level upper limit on this product for quantum black holes with threshold mass above 3.5 TeV is 0.18 fb . This limit constrains the threshold quantum black-hole mass to be above 5.3 TeV in the model considered.

Search for Quantum Black Hole Production in High-Invariant-Mass Lepton+Jet Final States Using pp Collisions at $\sqrt{s} = 8$ TeV and the ATLAS Detector

The ATLAS Collaboration

This Letter presents a search for quantum black-hole production using 20.3 fb^{-1} of data collected with the ATLAS detector in pp collisions at the LHC at $\sqrt{s} = 8$ TeV. The quantum black holes are assumed to decay into a final state characterized by a lepton (electron or muon) and a jet. In either channel, no event with a lepton-jet invariant mass of 3.5 TeV or more is observed, consistent with the expected background. Limits are set on the product of cross sections and branching fractions for the lepton+jet final states of quantum black holes produced in a search region for invariant masses above 1 TeV. The combined 95% confidence level upper limit on this product for quantum black holes with threshold mass above 3.5 TeV is 0.18 fb. This limit constrains the threshold quantum black-hole mass to be above 5.3 TeV in the model considered.

Quantum black holes (QBHs) [1, 2] are predicted in low-scale quantum gravity theories that offer solutions to the mass hierarchy problem of the Standard Model (SM) by lowering the scale of quantum gravity (M_D) from the Planck scale ($\sim 10^{16}$ TeV) to a value of about 1 TeV. In models with large extra dimensions such as the Arkani-Hamed–Dimopoulos–Dvali (ADD) model [3–5], only the gravitational field is allowed to penetrate the n extra dimensions, while all SM fields are localized in the usual four-dimensional space-time. QBHs with masses near M_D , postulated to conserve total angular momentum, color and electric charge, may decay to two particles [2, 6]. The behavior of QBHs is distinct from semi-classical black holes that decay via Hawking radiation to a large number of objects [7]. Searches for semi-classical black holes typically require three or more objects [8, 9].

The quantum approximations used in the modeling of black hole production are valid when black-hole masses are above a minimal threshold mass, M_{th} , which is taken to be equivalent to the QBH inverse gravitational radius. If the QBHs investigated in this Letter are accessible at the Large Hadron Collider (LHC) [10], they can produce lepton+jet final states [2, 6] motivating this first dedicated search for high-invariant-mass final states with a single electron (e) or a single muon (μ), and at least one jet. Two-particle QBH decays to a final state consisting of a lepton and a quark-jet violate lepton and baryon number conservation, producing a distinctive signal for physics beyond the SM. Previous searches for QBHs relied on signatures such as dijet mass distributions [11, 12], generic multiobject configurations [9] and photon+jet final states [13].

The largest QBH cross section for the final states considered is predicted for the collision of two u -quarks (σ_{uu}), which produces charge $+4/3$ objects with equal branching fractions (BFs) of $\text{BF}_{uu} = 11\%$ to each lepton+jet final state. The next largest cross sections are for charge $+1/3$ (ud) and $-2/3$ (dd) QBHs with lepton+jet BFs of $\text{BF}_{ud} = 5.7\%$ and $\text{BF}_{dd} = 6.7\%$ [6]. Processes with initial states having antiquarks and heavier sea-

quarks are suppressed by at least a factor of 100 and can be neglected. The QBH cross section is a steeply declining function of M_{th} , and has $\Sigma\sigma_{\text{qq}} \times \text{BF}_{\text{qq}} \approx 8.6 \times 10^5$ fb, 8.9×10^2 fb and 0.75 fb for M_{th} of 1 TeV, 3 TeV and 5 TeV, respectively [14].

The ATLAS detector [15] includes an inner tracker, covering a pseudorapidity [16] range $|\eta| < 2.5$, surrounded by a superconducting solenoid providing a 2 T central field. A liquid-argon (LAr) electromagnetic (EM) sampling calorimeter ($|\eta| < 3.2$), a scintillator-tile hadronic calorimeter ($|\eta| < 1.7$), a LAr hadronic calorimeter ($1.4 < |\eta| < 3.2$), and a LAr forward calorimeter ($3.1 < |\eta| < 4.9$) provide the energy measurements. The muon spectrometer consists of tracking chambers covering $|\eta| < 2.7$, and trigger chambers covering $|\eta| < 2.4$, in a magnetic field produced by a system of air-core toroids. Events considered in this analysis are required to have one high-transverse-momentum (high- p_T) lepton (e/μ) that passes requirements of the three-level trigger system [17]. The thresholds applied at the third trigger level are 60 GeV and 36 GeV for electrons and muons, respectively. The analysis is based on the complete 2012 data set of pp collisions taken at a center-of-mass energy of $\sqrt{s} = 8$ TeV by the ATLAS detector at the LHC, corresponding to an integrated luminosity of $20.3 \pm 0.6 \text{ fb}^{-1}$ [18] after data-quality requirements.

The event selection is designed to be efficient for generic lepton+jet final states and is based on leading-order simulated-signal QBH events obtained from the QBH1.04 generator [14], followed by parton showering and hadronization using PYTHIA8.165 [19]. The signal generator uses the MSTW2008LO [20] set of leading-order parton distribution functions (PDFs) with the AU2 underlying-event tune [21]. This Letter assumes the ADD model with $M_{\text{th}} = M_D$, $n = 6$, and the QCD factorization scale for the PDFs set to the inverse gravitational radius [14]. Samples with M_{th} from 1 TeV to 6 TeV, in steps of 0.5 TeV, are generated for both channels.

Events with a high- p_T lepton and one or more jets can also arise from electroweak (EW) processes includ-

ing vector-boson production with additional jets; diboson (WW, WZ, ZZ), top-quark pair ($t\bar{t}$) and single top-quark (t or \bar{t}) production; and multijet processes including non-prompt leptons from semileptonic hadron decays and jets misidentified as leptons.

The EW background in the signal region (SR) is estimated using Monte Carlo (MC) samples normalized to data in control regions. All MC simulated samples are produced using the ATLAS detector simulation [22] based on GEANT4 [23]. The simulated events are reconstructed in the same manner as the data. The $t\bar{t}$ and single-top-quark events are simulated with MC@NLO4.06 [24] and AcerMC3.8 [25], respectively; the production of W +jets and Z +jets is simulated using ALPGEN2.14 [26]; and diboson production is simulated with SHERPA1.4.1 [27]. The leading-order CTEQ6L1 PDFs [28] are used for ALPGEN and AcerMC samples while the next-to-leading-order CT10 PDFs [29] are used for the SHERPA and MC@NLO samples. The generators for all samples except dibosons are interfaced to HERWIG6.520 [30, 31] for parton showering and hadronization and to JIMMY4.31 [32] for the underlying-event model. The results of higher-order calculations are used to adjust the relative fractions of the simulated events as in Refs. [33, 34]. Additional inelastic pp interactions, termed pileup, are included in the event simulation so as to match the distribution in the data (on average 21 interactions per bunch crossing).

Electron candidates are identified as localized depositions of energy in the EM calorimeter with $p_{T_e} > 130$ GeV and $|\eta| < 2.47$, excluding the barrel-endcap transition region, $1.37 < |\eta| < 1.52$, and matched to a track reconstructed in the tracking detectors. Background from jets is reduced by requiring that the shower profiles are consistent with those of electrons [35]. Isolated electrons are selected by requiring the transverse energy deposited in a cone of radius $\Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2} = 0.3$ centered on the electron cluster, excluding the energy of the electron cluster itself, to be less than $0.0055 \times p_{T_e} + 3.5$ GeV after corrections for energy due to pileup and energy leakage from the electron cluster into the cone. This criterion provides nearly constant selection efficiency for signal events over the entire p_{T_e} range explored and for all the pileup conditions.

Muon candidates are required to be detected in at least three layers of the muon spectrometer and to have $p_{T_\mu} > 130$ GeV and $|\eta| < 2.4$. Possible background from cosmic rays is reduced by requiring the transverse and longitudinal distances of closest approach to the interaction point to be smaller than 0.2 mm and 1.0 mm, respectively. Signal muons are required to be isolated such that $\sum p_T < 0.05 \times p_{T_\mu}$, where $\sum p_T$ is the sum of the p_T of the other tracks in a cone of radius $\Delta R = 0.3$ around the direction of the muon.

Jets are constructed from three-dimensional noise-suppressed clusters of calorimeter cells using the anti- k_t

algorithm with a radius parameter of 0.4 [36, 37]. Jet energies are corrected for losses in material in front of the active calorimeter layers, detector inhomogeneities, the non-compensating nature of the calorimeter, and pileup. Jet energies are calibrated using MC simulation and the combination of several in-situ techniques applied to data [38–40]. All jets are required to have $p_{T_j} > 50$ GeV and $|\eta| < 2.5$. In addition, the most energetic jet is required to have $p_{T_j} > 130$ GeV.

The missing transverse momentum (with magnitude E_T^{miss}), used only in the background estimation, is calculated as the negative of the vectorial sum of calibrated clustered energy deposits in the calorimeters, and is corrected for the momenta of any reconstructed muons [41].

In the electron (muon) channel, events are required to have exactly one electron (muon). Multijet background can be reduced, with minimal loss in signal efficiency, by requiring the average value of η for the lepton and leading jet to satisfy $|\langle\eta\rangle| < 1.25$ and the difference between the lepton and leading jet η to satisfy $|\Delta\eta| < 1.5$. The signal lepton and jet are mostly back-to-back in ϕ and are required to satisfy $|\Delta\phi| > \pi/2$.

The invariant mass (m_{inv}) is calculated from the lepton and highest- p_T jet. The SR is defined by a lower bound on m_{inv} , m_{min} , that accounts for experimental resolution. In the electron channel $m_{\text{min}} = 0.9M_{\text{th}}$ is used. In the muon channel, the requirement is loosened at high invariant mass, as muon resolution has a term quadratic in p_{T_μ} , resulting in $m_{\text{min}} = [0.95 - 0.05M_{\text{th}}/1\text{TeV}] M_{\text{th}}$. A low-invariant-mass control region (LIMCR) is defined with m_{inv} between 400 GeV and 900 GeV, which has a negligible contamination from a potential signal ($< 2\%$) for the lowest M_{th} considered.

The acceptance of the event selection is about 65%, based on generator-level quantities and calculated by imposing selection criteria that apply directly to phase space (lepton/jet η , lepton/jet p_T , $\Delta\eta$, $\Delta\phi$, $\langle\eta\rangle$, and m_{inv}). All other selection criteria, which in general correspond to event and object quality requirements, are used to calculate the experimental efficiency based on the events included in the acceptance. The experimental efficiency falls from 89(59)% to 81(50)% for masses from 1 TeV to 6 TeV in the electron (muon) channel. The experimental efficiency in the muon channel is lower than that in the electron channel because more stringent requirements are applied to ensure the best possible resolution on m_{inv} . The cumulative signal efficiency is the product of the acceptance and experimental efficiency.

In the electron channel, the multijet background is characterized by small values of E_T^{miss} , while EW background events can have large E_T^{miss} due to the production of high-momentum neutrinos. The discriminating power of E_T^{miss} is used to determine the normalization of the two backgrounds to the data in the LIMCR. The multijet template is taken from data in which electron candidates pass relaxed identification criteria but fail the normal

identification selection, and the EW template is taken from MC simulation where electron candidates pass the normal selection. The templates are fit to the E_T^{miss} distribution in the interval $[0, 150]$ GeV in five separate detector-motivated regions of η , to determine normalization factors for both the multijet and EW backgrounds.

To extrapolate both the multijet and EW background to the SR, functions of the form $p_1 x^{p_2+p_3 \ln(x)} (1-x)^{p_4}$ (with $x = m_{\text{inv}}/\sqrt{s}$ and fit parameters p_1-p_4) [42] are used and the contributions are scaled by the corresponding normalization factor derived in the LIMCR. A simple power-law fit, with p_3 and p_4 fixed to zero, adequately describes both data and simulation. This is used as the baseline, while p_3 and p_4 are allowed to vary as part of the evaluation of the systematic uncertainty.

In the muon channel, the multijet and EW backgrounds can be discriminated on the basis of the transverse impact parameter (d_0) distribution of the muon since multijet background is dominated by jets containing charm and bottom hadrons decaying to muons while EW backgrounds are dominated by prompt muons. The template for the EW background is selected using Z -boson decays to two muons while the template for multijet background is taken from muons that fail the isolation requirement. Both templates are taken from data. The templates are fit to the d_0 distribution in the interval $[-0.1, +0.1]$ mm to determine the normalization factors. The fraction of multijet background, 0.046 ± 0.005 , is neglected when extrapolating the background in SR. The procedure for extrapolating the EW background to the SR is the same as for the electron channel.

The background estimate in the SR, shown in Fig. 1, was not compared to data until the final fit method and parameters were fixed. The hatched area in Fig. 1 shows the total uncertainty in the background estimate, which is dominated by the systematic uncertainties. In extracting the limits, the fits described above are used to extrapolate the background into the high invariant-mass region.

The systematic uncertainties on the background are evaluated as a function of m_{inv} , and are dominated by uncertainties on the fits used to extrapolate the background to the highest m_{inv} , uncertainties on PDFs, and the choice of MC generator. Systematic uncertainties due to the choice of fitting functions are evaluated by fitting the m_{inv} spectrum with parameters p_3 and p_4 free and taking the difference between these fits and the fits with p_3 and p_4 fixed to zero. Additionally, SHERPA samples are used instead of ALPGEN and the fits are repeated. The uncertainty in the PDFs is estimated using a set of 44 PDF eigenvectors for CTEQ6.6 [43]. For each of the 44 sets, the background fits are repeated and the extrapolated backgrounds are estimated. To estimate the uncertainty in the multijet background in the electron channel, an alternative selection of background-enriched data events, based on photons, is used. The systematic uncer-

FIG. 1. Distribution of the invariant mass of the lepton and highest- p_T jet in (a) the electron+jet channel and (b) the muon+jet channel, for data (points with error bars) and for SM backgrounds (solid histograms). Overlaid are two examples of QBH signals. The sum of the uncertainties due to the finite MC sample size and from various sources of systematic uncertainty is shown by the hatched area. To extract the upper limit on the lepton+jet cross section, a fit to the invariant-mass distribution is performed, replacing the uncertainties due to MC sample size by the statistical uncertainties on the fit parameters.

tainties from the simulation of the detector response are associated with the jet and electron energy scales and resolutions, the muon momentum scale and resolution, and the trigger requirement. The combined uncertainty in the background prediction ranges from 16% (1 TeV) to 100% (6 TeV) for the electron channel and from 50% (1 TeV) to 170% (6 TeV) for the muon channel. Background systematic uncertainties for $M_{\text{th}} = 5$ TeV are given in Table I.

Uncertainties on the signal efficiency in each of the mass bins are associated with the requirements on $\Delta\eta$, $\Delta\phi$, $\langle\eta\rangle$, m_{inv} , and isolation. In addition, uncertainties on the detector simulation, mentioned above for the background, as well as the uncertainty in luminosity are taken into account. The combined uncertainty in the signal efficiency from these sources ranges from 3.5% at 1 TeV to

TABLE I. Breakdown of relative systematic uncertainties on the SM background for the threshold mass $M_{\text{th}} = 5$ TeV. The uncertainties are added in quadrature to obtain the total uncertainty.

3.9% at 6 TeV for the electron channel and from 3.6% at 1 TeV to 5.6% at 6 TeV for the muon channel. The cumulative efficiency, shown in Table II, is taken from the signal MC simulation for charge $+4/3$ QBHs. The differences in the efficiency between the charge $+4/3$ state and the other charged states are much smaller than the uncertainties mentioned above and are neglected. The effect of the 0.65% uncertainty in the LHC beam energy [44] is to change the QBH production cross section. Since the QBH cross section is nearly constant in M_{th}/\sqrt{s} this is effectively an uncertainty in M_{th} and has a negligible effect on the limits.

The observed numbers of events and the expected backgrounds, shown in Table II, are in agreement within the total uncertainty. There is no evidence for any excess. Upper limits on $\Sigma\sigma_{\text{qq}} \times \text{BF}_{\text{qq}}$ for the produc-

FIG. 2. The combined 95% C.L. upper limits on $\Sigma\sigma_{\text{qq}} \times \text{BF}_{\text{qq}}$ for QBHs decaying to a lepton and jet, as a function of M_{th} , assuming $M_{\text{D}} = M_{\text{th}}$ and $n = 6$ ADD extra dimensions. The limits take into account statistical and systematic uncertainties. Points along the solid black line indicate the mass of the signal where the limit is computed. Also shown are the $\pm 1\sigma$ and $\pm 2\sigma$ bands indicating the underlying distribution of possible limit outcomes under the background-only hypothesis. The predicted cross section for QBHs is shown as the solid curve.

tion of QBHs above M_{th} are determined in the interval 1–6 TeV assuming lepton universality and using the CLs method [45, 46], which is designed to give conservative limits in cases where the observed background fluctuates below the expected values. The statistical combination of the channels employs a likelihood function constructed as the product of Poisson probability terms describing the total number of events observed in each channel. Systematic uncertainties are incorporated as nuisance parameters into the likelihood through their effect on the mean of the Poisson functions and through convolution with their assumed Gaussian distributions. Correlations between channels are taken into account.

Figure 2 shows the 95% confidence level (C.L.) combined lepton+jet upper limit on the cross section times branching fraction for the production of QBHs as a function of M_{th} . Above 3.5 TeV, the limit is 0.18 fb. For the $n = 6$ QBH model assumed in this Letter, the 95% C.L. lower limit on M_{th} is 5.3 TeV. For $n = 2$, and all other model assumptions the same, the 95% C.L. lower limit on M_{th} is 4.7 TeV. Treating the channels separately, the 95% C.L. upper limit on the electron (muon)+jet $\Sigma\sigma_{\text{qq}} \times \text{BF}_{\text{qq}}$ above 3.5 TeV is 0.27 (0.49) fb, and the $n = 6$ lower limit on M_{th} is 5.2 (5.1) TeV.

In conclusion, a first search for two body lepton+jet final states with large invariant mass has been performed using 20.3 fb^{-1} of pp collisions recorded at $\sqrt{s} = 8$ TeV with the ATLAS detector at the LHC. In the invariant-mass region above 1 TeV the observed events are consistent with data-driven extrapolated backgrounds from the low-invariant-mass control region. Above 3.5 TeV the ex-

pected background drops below one event and the 95% C.L. upper limit on the electron (muon)+jet $\Sigma\sigma_{qq} \times \text{BF}_{qq}$ is 0.27 (0.49) fb. Assuming lepton universality, the 95% C.L. upper limit on the sum of the product of QBH lepton+jet production cross sections and branching fractions is 0.18 fb.

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.
